To: Mayor Gere  
City of Anacortes Council

Dear Mayor and Council,

I am a relatively new resident in this great community of Anacortes, although have been a Skagit County resident for over 8 years. I love being here and have enjoyed and promoted as many of the great resources and business establishments as possible.

Unfortunately, over half my time residing here has been during the COVID pandemic, which has understandably hindered my ability to patronize the restaurants here. When takeout was the only option for several months, I was very discouraged by the type of materials used by too many establishments to carry the food and beverage, let alone the automatic inclusion of condiments and utensils. These materials and items cannot be composted or recycled so there is an unnecessary contribution to the waste stream. In particular, Styrofoam is extra harmful to the environment and is essentially banned in most progressive communities.

While I can certainly appreciate the challenge in utilizing better food and beverage containers and shopping bag options, very little of the plastic materials is viable, even for recycling (if people are even recycling it). Waste Management has greatly limited acceptable plastics to recycle for a variety of reasons, which leaves us in a quandary. But we need to start addressing these issues to improve our responsibility as a community around conscious consumerism.

For starters, now that our options to enjoy our restaurants have expanded as we start 'phasing out' of the pandemic, I see this as a time for the City to:

- **Ban** Styrofoam containers
- **Insist** the use of compostable utensils, straws and containers for condiments, dressings, etc.
- **Encourage** the purveyors to ask the customer if they need utensils, straws, napkins and condiments before including in the order – perhaps consider charging for them (to offset cost)
- **Discourage** the automatic use of plastic bags for orders, especially single or small orders (just ask!)

A unified message from the City on this front would be very effective, especially if other local establishments (Gere-a-deli?) are highlighted as models of what is possible. The City could even launch an initiative with offerings of reusable products, like carry-out bags with the City logo and restaurant participants.

Thank you for the opportunity to hear my concerns, needed regulation, and reasonable solutions. Would be happy to help out.

Elizabeth Walker  
206.697.2418

## **Anacortes City Council Minutes - May 3, 2021**

### **Call to Order**

Mayor Laurie Gere called to order the Anacortes City Council meeting of May 3, 2021 at 6:00 p.m. Councilmembers Jeremy Carter, Anthony Young, Ryan Walters, Christine Cleland-McGrath, Carolyn Moulton, Bruce McDougall and Matt Miller all participated in the meeting in absentia via video conference.

### **Executive Session: Potential Litigation or Litigation per RCW 42.30.110(1)(i) (15 minutes)**

Mayor Gere announced that City Council and the City Attorney would convene in Executive Session per RCW 42.30.110 (i) for approximately 15 minutes to discuss potential litigation or litigation. The mayor advised that no final action would be taken in the Executive Session. Councilmembers Jeremy Carter, Anthony Young, Ryan Walters, Christine Cleland-McGrath, Carolyn Moulton, Bruce McDougall and Matt Miller attended the executive session.

At 6:20 p.m. the mayor called the meeting back into regular session.

### **Announcements and Committee Reports**

COVID-19 Update: Mayor Gere shared current case statistics and vaccination progress for Anacortes, Skagit County, Washington State, and the nation. She noted increasing case counts and hospitalizations across the state including in Skagit County.

Finance Committee: Mr. Walters reported from the committee meeting held the previous week. The topics discussed included planning for a virtual City Council budget retreat on May 27, 2021. He asked councilmembers to email their priorities and budget topics to Finance Director Steve Hoglund by May 10. No councilmember objected.

Lodging Tax Advisory Committee: Mr. Miller reported from the Committee meeting held the previous week. The topics discussed included funding additional parklets for Commercial Avenue restaurants. Mr. Miller said the LTAC had supported the request.

Public Works Committee: Ms. Moulton reported from the Committee meeting held earlier in the evening. The topics discussed included the upcoming presentation to Council on wastewater solids handling options and subsequent decisions and funding options, wastewater treatment plant incinerator needs, the new raw water clearwell at the water treatment plant, school zone flashing beacons, Sharpes Corner roundabout revisions planned by WSDOT, the interdepartmental effort to beautify the R Avenue corridor, and the bidding process for the CSO project.

### **Public Comment**

No one present wished to address the Council on any topic not already on the agenda.

### **Consent Agenda**

Mr. Miller moved, seconded by Mr. Walters, to approve the following Consent Agenda items. The motion carried unanimously by voice vote.

- a. Minutes of April 26, 2021
- b. Approval of claims in the amount of \$122,614.68

The following vouchers/checks were approved for payment:

EFT numbers: 100002 through 100032, total \$56,578.68

Check numbers: 99992 through 100001, total \$27,420.48

Wire transfer numbers: 280646 through 283688, total \$44,676.95

- c. Resolution 3030: Waiving the State Competitive Bidding Requirements for the Purchase of Fairbanks Nijhuis (aka Fairbanks Morse) Pumps, Parts, and Service
- d. Resolution 3031: Waiving the State Competitive Bidding Requirements for the Purchase of Foxboro Instrumentation

## **PUBLIC HEARINGS**

### **Continued Public Hearing: Ordinance 3087: Vacating right-of-way of a portion of 11th Street adjacent to blocks 242 and 243, "Map of the City of Anacortes" together with the West 10 feet of B Avenue adjacent to Lot 1 of block 243**

City Attorney Darcy Swetnam recapped this agenda item as presented and discussed by City Council at its April 19, 2021 regular meeting. She noted that the public hearing on this item remained open from April 19.

Mayor Gere invited members of the audience to comment on this agenda item.

Sean Noronha opposed the proposed vacation and warned against setting bad precedent by granting this vacation in exchange for a trail easement. He urged Council to work with the neighborhood to mitigate future impacts.

Rebecca Ivey urged Council to vote against the vacation which Ms. Ivey said violated city code. She suggested that this was a bad deal that would set unfortunate precedent for future easements and vacations.

No other members of the public wished to address Council.

Mr. McDougall inquired about the code section referred to by Ms. Ivey. Ms. Swetnam explained that AMC Chapter 12.50 had been updated since negotiations had begun for the proposed vacation several years prior. She explained the relevant provisions of that chapter.

The majority of councilmembers expressed a desire to vacate the requested portions of 11th Street (Segments 2 and 3) but not the requested portions of B Avenue (Segments 4 and 5). Ms. Swetnam indicated that staff would need to revise the ordinance and bring it back to Council for action at the next meeting. Mayor Gere directed staff to do so.

At approximately 7:04 p.m. Mayor Gere closed the public hearing on Ordinance 3087.

### **Continued Public Hearing: Critical Area Regulations Draft 3**

Planning Director Don Measamer introduced Senior Planner Tess Cooper to lead the continued discussion of this item by City Council, following the opening of the public hearing at the regular City Council meeting of April 19, 2021.

Ms. Cooper noted that the public comment period for this agenda item had closed on April 23, 2021. She advised that staff had subsequently compiled all comments received and prepared responses to those. Ms. Cooper displayed that comment document and reviewed it line by line. Ms. Cooper's slide presentation was added to the packet materials for the meeting.

**Anacortes City Council Minutes - May 3, 2021**

Mayor Gere invited members of the audience to comment on this agenda item.

Kyle Loring commented on several of the language changes proposed in his submitted comment letter.

Tom Glade commented on the characterization of the Ship Harbor wetland, the term passive recreation and the ACFL.

Brian Wetcher commented on evolving maps and inventories over time and the value of including those to establish a baseline against which to measure no net loss.

Mayor Gere left the public hearing open to the May 10, 2021 regular City Council meeting.

**Adjournment**

There being no further business, at approximately 9:03 p.m. the Anacortes City Council meeting of May 3, 2021 was adjourned.

**The following claims against the City of Anacortes have been preaudited and certified by the Clerk-Treasurer as ready for City Council approval at the May 10, 2021 City Council meeting:**

# City Council Contract Agenda Bill

**Meeting Date:** 5/10/2021    **Agenda Item:** 4c

**Subject:** Contract Award: Ambulance Billing Services #21-103-FIN-001

**Staff Contact:** Steve Hoglund

**Approved for Submittal to Council by:**  
Darcy Swetnam, City Attorney

**Action Type:** Contract Award

**Summary Statement:** City staff seeks City Council consent to award a contract to Systems Design West, LLC to provide billing insurance services and managing receivables for ambulance transports.

## **Background:**

1. **History:** Systems Design West has managed the city's ambulance billing since 2014. This agreement terminates and supersedes agreement #14-058-FIR-001 and incorporates modifications to electronic check deposits, \$1 price increase per transport, and other minor adjustments. An average annual cost over the last 5 years is \$40,741.
2. **Key Terms:**
  - The City will pay a not-to-exceed amount of \$23.00 per transport.
  - The agreement auto-renews until terminated.
3. **Competitive Bidding:** This work is considered a personal service and therefore not subject to any competitive bidding requirements.

**Previous Council/Committee Action:** N/A

**Competing Viewpoints Considered:** N/A

**Recommended Motion:** I move that City Council authorize the Mayor to sign a contract 21-103-FIN-001 with Systems Design West, LLC to provide Ambulance Billing Services.

**Alternative Actions:** Not approve the contract

**Attachments:** Contract 21-103-FIN-001

## PROFESSIONAL SERVICES AGREEMENT

This Professional Services Agreement ("Agreement") is made and entered into this 1st day of July, 2021 by and between, City of Anacortes ("Provider") having its principal location at 904 6th St Anacortes, WA 98221 and Systems Design West, LLC a Delaware limited liability company having their principal place of business located at 19265 Powder Hill Place NE Poulsbo, Washington 98370 hereinafter referred to as the ("Consultant"). Collectively the Provider and the Consultant shall be known as the "PARTIES".

### RECITALS:

(a) WHEREAS, the Provider and the Consultant desire to enter into a "Professional Services Agreement",

(b) NOW, THEREFORE, in consideration for the mutual obligations contained herein the Provider and the Consultant, each intending to be legally bound by this agreement, hereby mutually covenant and agree as follows:

1. SCOPE OF SERVICES. The Consultant shall provide to the Provider specific services related to the billing and payment processing of EMS patient transport services that are provided to the general public by the Provider. The following Scope of Services shall be incorporated into this contract as general services performed by the Provider and the Consultant under this agreement.

1.1 The Provider, with assistance from Consultant, shall apply for Provider Status or updated Status with Medicare, Medicaid, and all public and private insurances which will be billed as a part of this Scope of Services. The Provider is responsible for informing the Consultant of any subsequent changes that necessitate updates (e.g. changing an Authorized Official) so that Consultant may complete its duties. The Provider shall assist the Consultant to obtain the necessary certifications, numbers and documentation needed for Consultant to provide the services identified in sections 1.2 and 1.3 below, obtain and maintain credentials for payer websites that require vendor access to be given only through a Provider representative and facilitate access for the Consultant's representatives. The Provider agrees to furnish and assist the Consultant with the following:

(a) The Provider agrees to provide a complete and legible "PCR" (Patient Care Report) to the Consultant including patient name, address and pertinent billing and insurance information from the field, including a copy of the patient signature for authorization of benefits and responsibility for payment, authorizing billing of Medicare, Medicaid and any insurance the patient is a subscriber to. The original patient signature must be maintained by the Provider and made available to the Consultant and/or insurance payers upon request. The amounts to be billed will be determined by the Provider in the form of a resolution or ordinance to be incorporated into this agreement as an attachment exhibit. Any subsequent increases to established fees must be communicated to the Consultant, in writing, prior to the submission of affected PCRs. "Automatic" annual increases should be communicated in writing as dollar amounts for confirmation each year. PCRs must be sent using a NEMSIS compliant XML format, or an additional fee may be charged.

(b) The Provider agrees to furnish the Consultant with hospital ER forms (face/admit sheets) with demographic and insurance information attached to the PCR if requested by Consultant. Copies of any payments made directly to the Provider will be forwarded to the Consultant for accounting purposes in a timely manner. The Provider agrees to generate any refund checks due to overpayments identified by the Consultant directly to the payer to which the refund is due, based on detailed information provided by the Consultant. The Provider shall provide additional information as may be required by insurance companies or other agencies in order to facilitate the Consultant's obligations to the Provider.

(c) The Provider agrees to furnish to the Consultant to be made part of this agreement as an attachment: resolutions pertaining to this Scope of Services; specific write off policies; collections procedures; rates and fees to be charged by the Provider and administered by Consultant as part of the Scope of Services performed under this agreement. Provider agrees to inform Consultant of any subsequent changes to these documents in writing in advance of when the new policies, procedures and/or rates take effect.

(d) The Provider agrees to complete registration with Consultant's vendors as applicable for Consultant to be able to fulfill its obligations to Provider. Such vendors may include e-payment and merchant services portal, remote deposit capture services, and clearinghouse registration.

1.2 Upon receipt of the PCRs from the Provider, the Consultant shall: set up a patient account in Consultant's proprietary software application and create a patient record; perform all billing operations including follow up statements and any necessary rebilling of EMS patient transport services provided by the Provider to the subscriber's medical insurances, Medicare, Medicaid and any and all known secondary insurance providers; produce and forward CMS 1500 forms and/or electronic medical claims per payer's rules and regulations within the legal boundaries of all federal and state laws; produce and mail an initial invoice and subsequent statements to all private patient accounts on behalf of the Provider; file any applicable appeals to insurance payers and/or Medicare and Medicaid on behalf of the patient if necessary to pursue the claim. Provider shall maintain a system to reconcile the number of PCRs sent to Consultant monthly.

1.3 The Consultant shall: receive at its facilities all payments (except those directly deposited into the Provider's account by insurances and Medicare/Medicaid via EFT) Explanations of Benefits and Electronic Remittance Advices; account for all payments; deposit all funds directly into the Provider's "deposit only" account; forward deposit information to the Provider within 24 hours of such deposit; initiate and forward refund information and adjustments made on behalf of the patient's account to the Provider. The Consultant shall provide to the Provider a minimum of four (4) standard reports each month including: a) Aged Accounts Receivable b) Month End Summary c) Annual Collection Statistics d) Transaction Journal. These reports will include information related to amounts billed, amounts collected and uncollected, insurance and Medicare/Medicaid allowable and disallowable. For payments and remittances that are wholly electronic portal-based, Provider shall grant access to Consultant's representatives as needed for various payer portals.

1.4 The Consultant shall provide live customer service to Provider's patients via toll free phone numbers to answer patient billing questions Monday through Friday from 8:00am through 6:00 pm, Pacific Standard Time (except Federal holidays).

1.5 The Consultant shall provide all labor, materials and equipment necessary to perform the work specified in the above scope of services. The Consultant is responsible for ensuring any subcontractor or vendor agencies are fully licensed and qualified to perform such work. For subcontracted payment processing and merchant services, Consultant is responsible for ensuring subcontractor or vendor maintains PCI compliance, and that the vendor or Consultant must be able to provide a PCI compliance certificate to Provider annually, at most.

1.6 Additional services: Additional services not specified in this Scope of Services (e.g. transferred accounts, non-routine auditing, targeted trainings, paper PCRs) may be added for an additional fee agreed upon in writing.

2. FEES, EXPENSES, & PAYMENT. Providers will receive a monthly invoice. For and in consideration of the services provided by the Consultant identified above, the Provider shall pay to the Consultant an amount not to exceed \$23.00 per transport.

In addition, the Provider will pay actual postage at current USPS postage rates for patient invoices, statements, and Certified Mail PCS requests per the Scope of Services performed under this agreement. Provider shall remit payment for services rendered under this agreement to the Consultant within 30 days from receipt of Consultant's monthly invoice to the Provider. Progress invoices may be sent if there are significant delays in PCR receipt from the Provider. A \$50.00 minimum applies to all invoices. Price adjustments may occur from time to time, no more than annually, and with written notification from Consultant at least 90 days in advance.

3. PAYMENT OF TAXES. The Consultant shall be liable for any and all federal, state, and local sales, excise taxes and assessments as a result of the payment for services rendered under this agreement.

4. TERM OF AGREEMENT. The Consultant shall commence the work called for in this agreement on the date of the agreement and perform such work uninterrupted and automatically renew upon the anniversary date unless the agreement is terminated by either party (see Section 7). This agreement may be amended by the parties upon mutual agreement of terms and conditions with the acknowledgement of an amendment to the Professional Services Agreement to be signed by both parties of the agreement.

5. SCHEDULE OF ATTACHMENT EXHIBITS. The following attachments are acknowledged by the parties and made part of this Agreement.

1. Rates to be charged per transport [to be provided by the Provider]
2. Billing & Collection Policies to be administered [to be provided by the Provider]
3. Consultant's Certificate of Liability Insurance
4. Business Associate Agreement, signed by both parties

6. INDEPENDENT CONSULTANT STATUS. The Consultant performs this Agreement as an independent Consultant, not as an employee of Provider. Nothing herein contained shall be deemed or construed by the parties hereto, nor by any third party, as creating the relationship of principal and agent or of partnership or

of joint venture between the parties hereto, it being understood and agreed that neither method of computation of payment nor any other provision contained herein nor any acts of the parties hereto, shall be deemed to create any relationship between the parties hereto other than the relationship of Provider and an independent Consultant.

7. TERMINATION. Either party may terminate this agreement with a minimum of 60 days' written notice to the other party. The Consultant shall upon termination by either party provide 60 days of follow up service to the outstanding patient accounts including posting payments, making deposits, and two (2) months of follow up reports to the Provider. Consultant shall deliver and document the return of all documentation in Consultants possession as applicable.

8. INSURANCE. The Consultant shall maintain statutory minimum Worker's Compensation or Labor and Industry insurance as required by the laws of any state or country in which Services are performed. The Consultant will provide and make as part of this agreement as an attachment, a certificate of liability insurance with a minimum amount of commercial general liability of \$ 1,000,000 per occurrence and an aggregate of \$ 2,000,000 and maintain such insurance for the duration of this agreement. The Consultant shall provide an annual updated Certificate of Insurance to the Provider upon the policy expiration date. The Consultant shall provide notice to the Provider in the event the policy is cancelled or terminated for any reason prior to the policy expiration date. The Provider shall be named as an additional insured under the Consultant's Commercial General Liability insurance endorsement CG 20 10 10 01 or substitute endorsement providing at least as broad coverage.

9. END USER SOFTWARE LICENSE & CONFIDENTIAL INFORMATION. The term "CONFIDENTIAL INFORMATION AND SOFTWARE" shall mean: (i) any and all Information and proprietary software which is disclosed or provided by either party ("OWNER OF THE INFORMATION") to the other ("RECIPIENT") verbally, electronically, visually, or in a written or other tangible form which is either identified or should be reasonably understood to be confidential or proprietary; and (ii) Confidential Information may include, but not be limited to, trade secrets, computer programs, software, documentation, formulas, data, inventions, techniques, marketing plans, strategies, forecasts, client lists, employee information, and financial information, confidential information concerning Provider and Consultant's business or organization, as the parties have conducted it or as they may conduct it in the future. In addition, Confidential Information may include information concerning any of past, current, or possible future products or methods, including information about research, development, engineering, purchasing, manufacturing, accounting, marketing, selling, leasing, and/or software (including third party software).

9.1 TREATMENT OF CONFIDENTIAL INFORMATION. Provider's Confidential Information shall be treated as strictly confidential by Recipient and shall not be disclosed by Recipient to any third party except to those third parties operating under non-disclosure provisions no less restrictive than in this Section and who have a justified business "need to know". Provider shall protect the deliverables resulting from Services with the same degree of care. This agreement imposes no obligation upon the Parties with respect to Confidential Information which either party can establish by legally sufficient evidence: (a) was in the possession of, or was rightfully known by the Recipient without an obligation to maintain its confidentiality prior to receipt from Provider; (b) is or becomes generally known to the public without violation of this Agreement; (c) is obtained by Recipient in good faith from a third party having the right to disclose it without an obligation of

confidentiality; (d) is independently developed by Recipient without the participation of individuals who have had access to the Confidential Information; or (e) is required to be disclosed by court order or applicable law, provided notice is promptly given to the Provider and provided further that diligent efforts are undertaken to limit disclosure.

**9.2 CONFIDENTIALITY AND DISCLOSURE OF PATIENT INFORMATION.** Use and Disclosure of Protected Health Information. The parties hereto agree that in order for the Consultant to perform its duties as expected by the Provider, it will be necessary for the Consultant to use and disclose Protected Health Information ("PHI"), as such term is defined at 45 CFR §164.501. The parties of this agreement further acknowledge and make part of this agreement as an attachment to this agreement a "Business Associate Agreement" to be maintained and updated whenever applicable by either party of this agreement.

**9.3 PERMITTED AND REQUIRED USES AND DISCLOSURE OF PHI.** The Parties hereto agree that the Consultant may use and disclose PHI in order to carry out any Payment function covered under the definition of "Payment" contained in 45 CFR §164.501. The Parties hereto further agree that the Consultant may use or disclose PHI for any use or disclosure that is required by law.

**10. INDEMNITY.** Each Party ("INDEMNIFYING PARTY") shall indemnify and hold the other Party ("INDEMNIFIED PARTY") harmless against any third party claim, including costs and reasonable attorney's fees, in which the Indemnified Party is named as a result of the negligent or intentional acts or failure to act by the Indemnifying Party, its employees or agents, while performing its obligations hereunder, which result in death, personal injury, or tangible property damage. This indemnification obligation is contingent upon the Indemnified Party providing the Indemnifying Party with prompt written notice of such claim, information, all reasonable assistance in the defense of such action, and sole authority to defend or settle such claim.

**10.1** Notwithstanding any other provision of this agreement, no party shall be liable for (a) any special, indirect, incidental, punitive, or consequential damages, including loss of profits or business arising from or related to the services or other deliverables hereunder or a breach of this agreement, even if such party has been advised of the possibility of such damages; or (b) any damages (regardless of their nature) for any delay or failure by a party to perform its obligations under this agreement due to any cause beyond the such party's reasonable control.

**10.2** Notwithstanding any other provision of this agreement, the Consultant's liabilities under this agreement under any theory of liability, whether based in contract law, tort law, negligence (active or passive), product liability, indemnification or otherwise shall be limited to the direct damages recoverable by the Provider under law not to exceed one times the aggregate amount of fees paid by the Provider to Consultant for the services or other deliverables that gave rise to the claim or that are otherwise the subject of such claim in the one (1) year period preceding the event giving rise to the claim.

**11. SURVIVABILITY.** The terms of Section 8 and 9 shall survive termination of this Agreement. If the Parties have executed a separate agreement that contains confidentiality terms prior to or contemporaneously with this Agreement, those separate confidentiality terms shall remain in full force to the extent they do not

conflict. The "Business Associate Agreement" has terms incorporated to establish the continuance of covenants for the parties to disclose PHI for the continued operations of "Payment".

12. **WARRANTIES AND REPRESENTATIONS.** Each party warrants that it has the right and power to enter into this Agreement and an authorized representative has executed this Agreement. Consultant warrants that the Services will be performed in a professional and workmanlike manner in accordance with recognized industry standards. To the extent Services provided by Consultant are advisory; no specific result is assured or guaranteed. Consultant EXPRESSLY DISCLAIMS ALL OTHER REPRESENTATIONS OR WARRANTIES, WHETHER EXPRESSED OR IMPLIED.

13. **NOTICE.** Any notice, demand, request, consent, approval, or other communication that either party desires or is required to give to the other party related to any of the content of this agreement shall be presented in writing and served personally or sent by prepaid, first class mail to the addresses set forth below. Either party may change its address by notifying the other party of its change of address in writing.

Provider: City of Anacortes  
904 6th St  
Anacortes, WA 98221

Consultant: Systems Design West, LLC  
19265 Powder Hill Pl NE  
Poulsbo, WA 98370

14. **NONWAIVER.** No modification to this Agreement nor any failure or delay in enforcing any term, exercising any option, or requiring performance shall be binding or construed as a waiver unless agreed to in writing by both parties. No delay or omission of the right to exercise any power by either party shall impair any such right or power, or be construed as a waiver of any default or as acquiescence therein. One or more waivers of any covenant, term or condition of this Agreement by either party shall not be construed by the other party as a waiver of a subsequent breach of the same covenant, term or condition.

15. **APPLICABLE LAW.** The laws of the State of Washington shall govern the construction, validity, performance and enforcement of this Agreement. Venue as to any action, claim, or proceeding arising out of, or based upon this Agreement, including, but not limited to, any action for declaratory or injunctive relief, shall be the appropriate court in the State of Washington.

16. **CONFLICT OF INTEREST.** The Consultant covenants, warrants and represents that the Consultant or any employees of Consultant has no interest and shall not acquire any interest, direct or indirect, which would conflict in any manner with the subject matter or the performance of this Agreement. The Consultant further covenants, warrants and represents that in the performance of this Agreement, no person having any such interest shall be employed by the Consultant in the future.

17. **ASSIGNMENT.** This Agreement may be assigned by Consultant. Provider may assign this Agreement directly or by operation of law with the prior written consent of Consultant, which shall not be unreasonably withheld.

18. ENTIRE AGREEMENT. This Agreement and any schedules, appendices, attachments and exhibits attached hereto sets forth all of the covenants, promises, agreements, conditions and understandings between the parties hereto, and there are no covenants, promises, agreements, conditions or understandings, either oral or written, between them other than as herein set forth. Except as herein otherwise expressly provided, no contemporaneous or subsequent agreement, understanding, alteration, amendment, change or addition to this Agreement, or any schedule, appendix, exhibit or attachment thereto shall be binding upon the parties of this Agreement hereto unless reduced to writing and signed by both parties. This Agreement constitutes a final, complete and exclusive statement of the agreement between the parties and supersedes any prior Agreements on the Effective Date. This agreement terminates and supersedes the Professional Services Agreement between the parties dated 12/19/2013 and identified as City of Anacortes #14-058-FIR-001.

The Parties hereby agree to all of the above terms, conditions, covenants and have executed this Agreement by a duly authorized representative.

## **Business Associate Agreement Between City of Anacortes and Systems Design West, LLC**

This Business Associate Agreement (“Agreement”) between **City of Anacortes** (“Covered Entity”) and Systems Design West, LLC (“Business Associate”) is executed to ensure that Systems Design West, LLC will appropriately safeguard protected health information (“PHI”) and personally identifiable information (“PII”) that is created, received, maintained, or transmitted on behalf of the **City of Anacortes** in compliance with applicable federal, state, and local statutes, regulations, rules and policies—including but not limited to, the provisions of Public Law 104-191 of August 21, 1996, known as the Health Insurance Portability and Accountability Act of 1996, Subtitle F – Administrative Simplification, Sections 261, *et seq.*, as amended (“HIPAA”), and with the Public Law 111-5 of February 17, 2009, known as the American Recovery and Reinvestment Act of 2009, Title XII, Subtitle D – Privacy, Sections 13400, *et seq.*, the Health Information Technology and Clinical Health Act, as amended (the “HITECH Act”).

### **A. General Provisions**

1. **Meaning of Terms.** The terms used in this Agreement shall have the same meaning as those terms defined in HIPAA.
2. **Regulatory References.** Any reference in this Agreement to a regulatory section means the section currently in effect or as amended.
3. **Interpretation.** Any ambiguity in this Agreement shall be interpreted to permit compliance with HIPAA.

### **B. Catch-all Definition**

The following terms used in this Agreement shall have the same meaning as those terms in the HIPAA Rules: Breach, Data Aggregation, Designated Record Set, Disclosure, Health Care Operations, Individual, Minimum Necessary, Notice of Privacy Practices, Protected Health Information, Required By Law, Secretary, Security Incident, Subcontractor, Unsecured Protected Health Information, and Use.

#### **Specific definitions:**

- (a) **Business Associate.** “Business Associate” shall generally have the same meaning as the term “business associate” at 45 CFR 160.103, and in reference to the party to this agreement, shall mean Systems Design West, LLC.
- (b) **Covered Entity.** “Covered Entity” shall generally have the same meaning as the term “covered entity” at 45 CFR 160.103, and in reference to the party to this agreement, shall mean the **City of Anacortes**.
- (c) **HIPAA Rules.** “HIPAA Rules” shall mean the Privacy, Security, Breach Notification, and Enforcement Rules at 45 CFR Part 160 and Part 164.

### **C. Obligations of Systems Design West, LLC**

Systems Design West, LLC agrees to:

1. Use appropriate safeguards and comply, where applicable, with the HIPAA Security Rule with respect to electronic protected health information (“e-PHI”) and electronic personally identifiable information (“e-PII”) as well as implement appropriate physical, technical and administrative safeguards to prevent use or disclosure of PHI and PII other than as provided for by this Agreement;
2. Report to the Covered Entity any use or disclosure of PHI and PII not provided for by this Agreement of which it becomes aware, including any security incident (as defined in the HIPAA Security Rule) and any breaches of unsecured PHI and PII as required by 45 CFR §164.410. Breaches of unsecured PHI and PII shall be reported to the Covered Entity and affected parties without unreasonable delay but in no case later than 30 days after discovery of the breach;
3. In accordance with 45 CFR 164.502(e)(1)(ii) and 164.308(b)(2), ensure that any subcontractors that create, receive, maintain, or transmit PHI and PII on behalf of Systems Design West, LLC agree to the same restrictions, conditions, and requirements that apply to Systems Design West, LLC with respect to such information;
4. Make PHI and PII in a designated record set available to the Covered Entity and to an individual who has a right of access in a manner that satisfies the Covered Entity’s obligations to provide access to PHI and PII in accordance with 45 CFR §164.524 within 30 days of a request;
5. Make any amendment(s) to PHI and PII in a designated record set as directed by the Covered Entity, or take other measures necessary to satisfy the Covered Entity’s obligations under 45 CFR §164.526;
6. Maintain and make available information required to provide an accounting of disclosures to the Covered Entity or an individual who has a right to an accounting within 60 days and as necessary to satisfy the Covered Entity’s obligations under 45 CFR §164.528.
7. To the extent that Systems Design West, LLC is to carry out any of the Covered Entity’s obligations under the HIPAA Privacy Rule, Systems Design West, LLC shall comply with the requirements of the Privacy Rule that apply to the Covered Entity when it carries out that obligation;
8. Make its internal practices, books, and records relating to the use and disclosure of PHI and PII received from, or created or received by Systems Design West, LLC on behalf of the Covered Entity, available to the Secretary of the Department of Health and Human Services for purposes of determining Systems Design West, LLC and the Covered Entity’s compliance with HIPAA and the HITECH Act;
9. Restrict the use or disclosure of PHI and PII if the Covered Entity notifies Systems Design West, LLC of any restriction on the use or disclosure of PHI and PII that the Covered Entity has agreed to or is required to abide by under 45 CFR §164.522; and
10. If the Covered Entity is subject to the Red Flags Rule (found at 16 CFR §681.1 *et seq.*), Systems Design West, LLC agrees to assist the Covered Entity in complying with its Red Flags Rule obligations by: (a) implementing policies and procedures to detect relevant Red Flags (as defined

under 16 CFR §681.2); (b) taking all steps necessary to comply with the policies and procedures of the Covered Entity's Identity Theft Prevention Program; (c) ensuring that any agent or third party who performs services on its behalf in connection with covered accounts of the Covered Entity agrees to implement reasonable policies and procedures designed to detect, prevent, and mitigate the risk of identity theft; and (d) alerting the Covered Entity of any Red Flag incident (as defined by the Red Flag Rules) of which it becomes aware, the steps it has taken to mitigate any potential harm that may have occurred, and provide a report to the Covered Entity of any threat of identity theft as a result of the incident.

11. Comply with all current rules and regulations pertaining to the OIG Compliance Program for ambulance suppliers and special bulletin regarding LEIE recommended screening of employees and any subcontractors.

**D. Permitted Uses and Disclosures by Systems Design West, LLC**

Systems Design West, LLC may use or disclose PHI and PII as required by law and consistent with the Minimum Necessary standard—specifically, the use and disclosure of PHI and PII will be limited to the minimum necessary for accomplishing the intended purpose of the use and disclosure. The specific uses and disclosures of PHI and PII that may be made by Systems Design West, LLC on behalf of the Covered Entity include:

1. The preparation of invoices to patients, carriers, insurers and others responsible for payment or reimbursement of the services provided by the Covered Entity to its patients;
2. Preparation of reminder notices and documents pertaining to collections of overdue accounts;
3. The submission of supporting documentation to carriers, insurers and other payers to substantiate the healthcare services provided by the Covered Entity to its patients or to appeal denials of payment for the same; and
4. Other uses or disclosures of PHI and PII as permitted by HIPAA necessary to perform the services that Systems Design West, LLC has been engaged to perform on behalf of the Covered Entity.

**E. Termination**

1. The Covered Entity may terminate this Agreement if the Covered Entity determines that Systems Design West, LLC has violated a material term of this Agreement.
2. If either party knows of a pattern of activity or practice of the other party that constitutes a material breach or violation of the other party's obligations under this Agreement, that party shall take reasonable steps to cure the breach or end the violation, as applicable, and, if such steps are unsuccessful, terminate the Agreement if feasible.
3. Upon termination of this Agreement for any reason, Systems Design West, LLC shall return to the Covered Entity or destroy all PHI and PII received from the Covered Entity, or created, maintained, or received by Systems Design West, LLC on behalf of the Covered Entity that Systems Design West, LLC still maintains in any form. Systems Design West, LLC shall retain no copies of the PHI and PII. If return or destruction is infeasible, the protections of this Agreement will extend to such PHI.

# City Council Contract Agenda Bill

**Meeting Date:** 5/10/2021    **Agenda Item:** 4d

**Subject:** Resolution 3034 – Declaring an Emergency and Waiving State Competitive Bidding Requirements for the Repair of 41<sup>st</sup> Street

**Staff Contact:** Fred Buckenmeyer

**Approved for Submittal to Council by:**  
Darcy Swetnam, City Attorney

**Action Type:** Resolution

**Summary Statement:** City staff seeks City Council approval of Resolution 3034 to declare an emergency and waive state competitive bidding requirements for the repair of 41<sup>st</sup> Street.

**Background:**

- RCW 39.04.280 provides that the City, by resolution, may waive competitive bidding requirements for public works in the event of an emergency. For purposes of RCW 39.04.280, an “emergency” is any unforeseen circumstance beyond the control of the municipality that either (a) presents a real, immediate threat to the proper performance of essential functions; or (b) will likely result in material loss or damage to property, bodily injury, or loss of life if immediate action is not taken.
- A large sag in the pavement on 41st Street between Cherry Lane and H Avenue had been forming and upon opening up the pavement the Street Department discovered a 10’ wide x 10’ long x 3’ deep void in the subgrade under the asphalt across the entire westbound traffic lane.
- A significant amount of ground water appears to be being intercepted by and routed down the Sanitary Sewer line in 41st Street. Then when the road levels out the water seeks weak spots in the roadway subgrade and surface to relieve the pressure created by gravity coming down the hill.
- The Street Department has been battling this groundwater and resulting pavement failures regularly over the past six months. They have had the entire crew onsite for at least 8 days total over 3 different events since September, one event in September, one event in October, and one in February. The repairs made in September and October are already showing signs of failure in the pavement surface and are likely to need further repair in the coming months.
- No stormwater system exists in this area on the north side of 41st Street. The existing water in the ditch on the North side of 41st Street that flows easterly down the hill is currently being collected by a catch basin installed by a homeowner during their house construction at 1817 41st street and routed via a 4” pipe through a private drainage easement through the 40th Court subdivision.
- This portion of 41st Street is in a state of imminent potential for total failure causing property damage, bodily injury, and becoming a risk to human health.
- Repair and installation of the road, pipes, and stormwater system is “public work” as defined by RCW 39.04.010(4).

**Previous Council/Committee Action:** N/A

**Competing Viewpoints Considered:** N/A

**Recommended Motion:** I move that the Resolution 3034 be approved declaring an emergency and waiving state competitive bidding requirements for the repair of 41<sup>st</sup> Street, pursuant to RCW 39.04.280.

**Alternative Actions:** N/A

**Attachments:** Resolution 3034

## RESOLUTION 3034

### **A RESOLUTION OF THE CITY COUNCIL OF THE CITY OF ANACORTES, WASHINGTON, declaring an emergency and waiving state competitive bidding requirements for the repair of 41<sup>st</sup> Street, pursuant to RCW 39.04.280.**

WHEREAS, RCW 39.04.280 provides that the City, by resolution, may waive competitive bidding requirements for public works in the event of an emergency. For purposes of RCW 39.04.280, an “emergency” is any unforeseen circumstance beyond the control of the municipality that either (a) presents a real, immediate threat to the proper performance of essential functions; or (b) will likely result in material loss or damage to property, bodily injury, or loss of life if immediate action is not taken; and

WHEREAS, a large sag in the pavement on 41<sup>st</sup> Street between Cherry Lane and H Avenue had been forming and upon opening up the pavement the Street Department discovered a 10’ wide x 10’ long x 3’ deep void in the subgrade under the asphalt across the entire westbound traffic lane; and

WHEREAS, a significant amount of ground water appears to be being intercepted by and routed down the Sanitary Sewer line in 41st Street. Then when the road levels out the water seeks weak spots in the roadway subgrade and surface to relieve the pressure created by gravity coming down the hill; and

WHEREAS, the Street Department has been battling this groundwater and resulting pavement failures regularly over the past six months. They have had the entire crew onsite for at least 8 days total over 3 different events since September, one event in September, one event in October, and one in February. The repairs made in September and October are already showing signs of failure in the pavement surface and are likely to need further repair in the coming months; and

WHEREAS, no stormwater system exists in this area on the north side of 41st Street. The existing water in the ditch on the North side of 41st Street that flows easterly down the hill is currently being collected by a catch basin installed by a homeowner during their house construction at 1817 41st street and routed via a 4” pipe through a private drainage easement through the 40th Court subdivision; and

WHEREAS, this portion of 41<sup>st</sup> Street is in a state of imminent potential for total failure causing property damage, bodily injury, and becoming a risk to human health.; and

WHEREAS, repair and installation of the road, pipes, and stormwater system is “public work” as defined by RCW 39.04.010(4).

NOW, THEREFORE, BE IT RESOLVED by the City Council of the City of Anacortes, Washington as follows:

Section 1. The City Council of the City of Anacortes, Washington finds that the facts set forth in the recitals of this resolution are true and that the failure of the roadway due to the lack of a stormwater system on 41<sup>st</sup> Street constitutes an

emergency under RCW 39.04.280. Pursuant to RCW 39.04.280, the City Council hereby declares and certifies that an emergency exists requiring immediate repair and reconstruction of the road and installation of a stormwater system on 41<sup>st</sup> Street.

Section 2. The City Council of the City of Anacortes, Washington hereby waives the bidding requirements and authorizes staff to contract without solicitation of bids for the public work project titled 41<sup>st</sup> Street Repairs, and to take such actions as necessary to carry out the intent and direction of this Resolution.

Section 3. Any actions of the City or its officers prior to the date hereof and consistent with the terms of this Resolution are ratified and confirmed.

Section 4. This Resolution shall be in full force and effect from the after its adoption and approval.

The foregoing resolution was ADOPTED by the City Council of the City of Anacortes, Washington, at a regular, open public meeting thereof this 10<sup>th</sup> day of May 2021.

## City Council Agenda Bill

**Meeting Date:** May 10, 2021

**Agenda Item:** 4.e.

**Agenda Item Title:** Street Fair Application: Anacortes Farmers Market

**Staff Contact(s):** DON MEASAMER, Joann Stewart

| <b><u>Approved for Submittal to Council by</u></b> | <b><u>Action Type</u></b> |
|----------------------------------------------------|---------------------------|
| Joann Stewart                                      | Motion                    |

**Item Summary:** Approve closure of street (R Avenue between 6th & 7th Streets) for expanded access to weekly farmers market

**Budget Impact:**

No impact to budget

**Previous Action:** Application routed to Department Heads and approved prior to City Council review; annual approval for street closure

**Recommended Motion:** I move to approve the proposed street fair application as submitted.

**Alternative Actions:** Deny request

**Attachments (listed in order presented):**

{{(++counter).ToString()}. {itemDocument.FileName}}

{{(++counter).ToString()}. {itemDocument.FileName}}

## Street Fair Application Processing

Administrator reviews the application for completeness. Administrator contacts the applicant to obtain any missing information and updates the application accordingly, including a legible copy of the Indemnification Agreement if that was not provided. It is recommended that the Administrator also verify that the applicant has entered phone and email correctly! Administrator then sets the target City Council date and routes the application for review by department heads.

## SPECIAL EVENT INDEMNIFICATION AGREEMENT

The undersigned applicant, by signing below, certifies that the applicant is the authorized officer of the sponsoring organization and agrees as follows:

Pursuant to Anacortes Municipal Code Title 7.04.090, the undersigned applicant agrees to defend, indemnify and hold the City of Anacortes, its agents, employees and officers, harmless from any and all claims, injuries, suits, damages, losses, demands and judgments including the attorneys' fees and other costs of their defense, arising out of in whole or in part, the activities, omissions or appliances of the applicant, his employees, agents, volunteers or otherwise, except any claims arising from the sole negligence of the City. The applicant further agrees to comply with all provisions of pertinent laws, rules and regulations, and agrees that any failure to so comply may lead to revocation of an applicant's permit. This Indemnification Agreement constitutes substantial adequate consideration in return for the City's issuance of a special event permit.

## City Council Agenda Bill

**Meeting Date:** May 10, 2021

**Agenda Item:** 5.a.

**Agenda Item Title:** Ordinance 3087: Vacating right-of-way of a portion of 11th Street adjacent to blocks 242 and 243, "Map of the City of Anacortes"

**Staff Contact(s):** DARCY SWETNAM

**Approved for Submittal to Council by**   **Action Type**

DARCY SWETNAM

Ordinance

STEVE HOGLUND

**Item Summary:** Ordinance 3087 as drafted vacates right-of-way that consists of a portion of 11th Street adjacent to blocks 242 and 243, "Map of the City of Anacortes".

In exchange for the vacation of 11th Street, the Property Agreement between the City, the Wynn Family Trust, and the Ortman Family LLCs, provides that the Wynn Family Trust will grant the City an easement across their property for the future construction and placement of the Guemes Channel Trail. The original proposal also anticipated vacating a 10' strip along B Avenue, but Council determined that partial vacation was prohibited by Section 12.50.070 AMC.

**Budget Impact:**

N/A

**Previous Action:** The City Council passed [Resolution 3017](#) at the [March 1, 2021](#) City Council meeting. This set a public hearing to be heard on the proposed vacation on April 5, 2021. On [April 5, 2021](#) the public hearing was continued to April 19, 2021. On [April 19, 2021](#) City Council conducted a site visit and then received public comment at the public hearing during the regular meeting. The public hearing was continued to [May 3, 2021](#) and closed at the conclusion of public comments.

**Recommended Motion:** I move to adopt Ordinance 3087 vacating right-of-way of a portion of 11th Street adjacent to blocks 242 and 243, "Map of the City of Anacortes".

**Alternative Actions:** Propose alternative language, decline to take action.

Anacortes, WA 98221

**ORDINANCE NO. 3087**

**AN ORDINANCE VACATING RIGHT-OF-WAY OF A PTN. OF 11TH STREET  
ADJACENT TO BLOCKS 242 AND 243, "MAP OF THE CITY OF ANACORTES"**

**THE CITY COUNCIL OF THE CITY OF ANACORTES DOES HEREBY ORDAIN AS  
FOLLOWS:**

**WHEREAS**, per AMC Chapter 12.50 Street and Alley Vacation the City Council, a hearing on the petition or proposal held before the City Council shall be upon the day fixed by resolution or at the time to which a hearing may be adjourned; and

**WHEREAS**, at the March 1, 2021, City Council meeting a resolution was passed to set a hearing date for April 5, 2021, to consider a petition to vacate right-of-way on 10th Street; and

**WHEREAS**, the City Council opened the public hearing on said proposal on April 5, 2021 fixed by Resolution 3017 and continued the public hearing to April 19, 2021, and again to May 3, 2021, and agreed to approve the proposal as set-forth below; and

**WHEREAS**, the City and property owners have entered into a certain Property Agreement, dated December 21, 2020, which provides that, in exchange for the vacation of certain portions of unopened City right-of-way, the City will obtain easements for a public trail along the Guemes Channel waterfront; and

**WHEREAS**, the City hereby finds that a vacation of the end of 11<sup>th</sup> Street will provide a significant benefit to the public in the form of increased access to trail easements for the future Guemes Channel Trail; and

**WHEREAS**, the City hereby finds the end of 11<sup>th</sup> Street is neither currently required for public use or public access nor anticipated to be needed for public use or access in the future; and

**WHEREAS**, the City hereby concludes that the substitution of a new and different public way along the Guemes Channel Trail in the future would be more useful to the public; and

**WHEREAS**, the City hereby finds no possible future public uses to 11<sup>th</sup> Street which may require this right-of-way; and;

**WHEREAS**, the City has considered all objections to the proposed vacation; and

**WHEREAS**, the City hereby finds that Section 12.50.070 AMC, which was adopted in 2020, prohibits the vacation of the proposed strip of right-of-way along B Avenue because the criteria for an exception to the general prohibition against partial vacations provided in Section 12.50.070(B) AMC have not been met, specifically because the vacation of the entire width of B Avenue is possible and the requested partial vacation does not adequately addresses all factors in AMC 12.50.060; and

**WHEREAS**, the City hereby finds that the proposed compensation meets the requirements of AMC Chapter 12.50; now, therefore

**THE CITY COUNCIL OF THE CITY OF ANACORTES, DOES HEREBY ORDAIN AS FOLLOWS:**

**SECTION 1.** Findings of Fact and Conclusions of Law.

All of the recitals are hereby adopted as findings and conclusions.

**SECTION 2.** Vacations.

The street and alley right-of-way areas within the City of Anacortes described in Exhibit A should be and are hereby vacated.

**SECTION 2.** Compensation.

Compensation for the vacation shall be in the form of an easement from the Wynn Family Trust for trail purposes. The easement area to be conveyed to the City as compensation are described in Exhibit B.

**SECTION 4.** Effective Date: This ordinance shall take effect 5 (five) days after execution and recording of the easement described in Section 2 above and publication as required by law.

**PASSED AND APPROVED** this 10<sup>th</sup> day of May 2021.

### **LEGAL DESCRIPTION VACATION #3**

#### **TO P56380 ANACORTES 3 LLC**

That portion of Government Lot 5, Section 13, and the Northwest  $\frac{1}{4}$  of Section 24, Township 35 North, Range 01 East of the Willamette Meridian more particularly described as follows:

The South  $\frac{1}{2}$  of 11<sup>th</sup> Street lying southerly of Block 242, MAP OF THE CITY OF ANACORTES, per plat recorded in Volume 2 of Plats, pages 4 through 7 inclusive, records of Skagit County, Washington and lying Northerly of Parcel D as described and shown on Record of Survey recorded on July 02, 2013, under Auditors file number 201307020094 records of Skagit County, Washington, and lying Easterly of Parcel B and Parcel C as described and shown on said Record of Survey recorded on July 02, 2013 and lying Westerly of a line beginning at the Southeast corner of said Block 242 and extending to the Northeast corner of Parcel D as described and shown on said Record of Survey recorded on July 02, 2013.

### **Exhibit B: Easement Area**

That portion of the Burlington Northern Railroad designated as reserve right-of-way for the Seattle and Northern Railroad as shown on the "MAP OF THE CITY OF ANACORTES, SKAGIT COUNTY, WASHINGTON", as per plat recorded in Volume 2 of Plats, page 4, records of Skagit County, Washington.

**TOGETHER WITH** a portion of Tract 14 of Plate No. 8 of the tide and shoreline of Section 13, Township 35 North, Range 1 East, W.M., Anacortes Harbor, all being more particularly described as follows:

Beginning at the intersection of 11<sup>th</sup> Street and "B" Avenue of said Plat; thence North 0°33'35" East along the Northerly projection of the centerline of "B" Avenue, a distance of 217.06 feet to the true point of beginning being an intersection with a curve having a radius point bearing North 20°46'49" West, a radial distance of 985.37 feet; thence Southwesterly along the arc of said curve to the right through a central angle of 2°58'54", an arc distance of 51.28 feet; thence South 72°12'05" West, a distance of 13.20 feet to the beginning of a curve to the left having a radius of 925.36 feet; thence along the arc of said curve through a central angle of 5° an arc distance of 81.88 feet; thence North 8°56'58" West, a distance of 70.47 feet; thence North 62°14'00" East, a distance of 169.11 feet to the intersection with the Northerly projection of the centerline of "B" Avenue; thence South 0°33'35" West, a distance of 98.99 feet to the true point of beginning.

**EXCEPT** the South 10 feet thereof.

**Property Agreement  
between the  
City of Anacortes  
and  
Property Owners.**

This Property Agreement ("Agreement") is entered into effective as of the last signature date by the undersigned parties below, by and between the City of Anacortes ("City"), a Washington municipal corporation, and Property Owners ("Wynn Family Trust, Ortman Family LLC, Anacortes 1 LLC, Anacortes 2 LLC, and Anacortes 3 LLC).

**RECITALS**

- A. The City is in the process of constructing a paved public trail along the Guemes Channel waterfront ("Trail") with a goal of connecting downtown Anacortes to Washington Park.
- B. The City desires to construct the Trail within the legally described boundaries of the Wynn and Ortman Properties described below. The City would like to obtain easements for the Trail.
- C. The Ortman Family, through Anacortes 1, LLC conveyed to the City of Anacortes an easement across the Ortman Properties, recorded on August 2, 2010, under Skagit County Auditor's File Number 201007230112 as a gift and for the construction, operation, maintenance, and repair of the Trail, which is legally described in Exhibit C, which is hereby incorporated by reference. .
- D. The City possesses certain portions of dedicated public right-of-way which are currently not used for streets, including B Avenue and 11<sup>th</sup> Street.
- E. The Ortman Family desires to add a portion of currently unvacated 11<sup>th</sup> Street and a portion of unvacated B Avenue to their properties at 1116 B Avenue, 2405 11<sup>th</sup> Street, 2401 11<sup>th</sup> Street, and 1114 B Avenue, all in Anacortes, Washington.
- F. The Wynn Family Trust desires to add a portion of currently unvacated 11<sup>th</sup> Street to its property at 2402 11<sup>th</sup> Street, Anacortes, Washington.
- G. The Properties that are the subject of this Agreement are as follows:
  - a. Ortman Properties:
    - i. Anacortes 1 LLC owns Skagit County Parcel P31488, legally described in Exhibit A, which is hereby incorporated by reference, hereinafter referred to as "Anacortes 1 Property".
    - ii. Anacortes 2 LLC owns Skagit County Parcel P56381, legally described in Exhibit A, hereinafter referred to as "Anacortes 2 Property".

- iii. Anacortes 3 LLC owns Skagit County Parcel P56380, legally described in Exhibit A, hereinafter referred to as "Anacortes 3 Property".
  - iv. Ortman Family LLC owns Skagit County Parcels P56382, P131777, and P31535, legally described in Exhibit A, hereinafter referred to as "Ortman Family LLC Properties".
  - v. The six parcels referenced above are hereby collectively referred to as "Ortman Property".
  - b. Wynn Property: The Wynn Family Trust owns Skagit County Parcels P31489, P 31538, and P56379, legally described in Exhibit A, hereinafter referred to as "Wynn Property".
- H. The Parties wish to work cooperatively to transfer ownership of various pieces of real property to keep the Parties whole and allow construction of the Trail.

## AGREEMENTS

NOW, THEREFORE, for good, valuable, and fair consideration, the adequacy and receipt of which are hereby acknowledged, the parties hereby Agree as follows.

- I. Purpose: The purpose of this Property Agreement is to allow the Parties to transfer certain interests in real property so that each Party achieves a desired adjustment to their real property interests and boundaries while allowing the City to proceed with construction of the Guemes Channel Trail.
- II. City Obligations
  - A. Vacation. Within ten (10) days following execution of this Agreement, the City will initiate and begin processing a Petition to vacate 5 separate portions of City right-of-way, legally described and depicted in Exhibit B, which is hereby incorporated by reference. Said vacation petition(s) must comply with all requirements of the Revised Code of Washington, the Anacortes Municipal Code, and the Anacortes Public Works and Planning Departments. The City cannot guarantee the outcome of vacation proceedings.
  - B. Insurance. The City will ensure any City property interest conveyed via easement to the City, including the Trail, during and after construction, is covered by the City's general liability coverage through Washington Cities Insurance Authority.

### III. Wynn Obligations

- A. Easement. In exchange for approximately 4,125 square feet of vacated right-of-way, within ten (10) days of City approval of the vacation, the Trustee of the Wynn Family Trust will convey on a form substantially similar to Exhibit D or by format approved by the City Attorney, an express easement over and across their property for construction and maintenance of the Guemes Channel Trail. The easement area to be conveyed is legally described on attached Exhibit C.

### IV. Ortman Obligations

- A. Easement. In exchange for approximately 4,906 square feet of vacated right-of-way, the Ortman Family has conveyed to the City of Anacortes an easement for the construction, operation, maintenance, and repair of the Trail. The easement area is legally described on attached Exhibit C.
- B. Vacation. The Ortman Family hereby agrees not to oppose any future Petitions to vacate the portion of 11<sup>th</sup> Street described as Vacation #2 in favor of the Wynn Family Trust.

### VII. Additional Terms

- A. Indemnification. The City agrees to indemnify, defend, and hold harmless the other Parties, their officers, agents, and employees from and against any and all claims, losses, actions or judgments for damages or injury to persons or property arising out of or in connection with the acts and/or performances or activities of the City, its agents, employees, representatives, or agents pursuant to this Agreements, except to the extent caused by the negligence of the other Party.
- B. Cooperation. The Parties will reasonably cooperate with each other to implement the terms of this Agreement, including but not limited to, executing documents and taking other action reasonably necessary to implement the terms of this Agreement.
- C. Captions or Interpretations. Paragraph titles or captions are inserted as a matter of convenience and for reference, and in no way define, limit, extend, or describe the scope of this Agreement or any provision.
- D. Modification or Amendment. This Agreement may not be changed, altered, or modified, except in writing and signed by the Parties.
- E. Severability. In the event any term or condition of this Agreement or application thereof to any person or circumstance is held invalid, such

invalidity shall not affect other terms, conditions or applications of this Agreement which can be given effect without the invalid term, condition or application. To this end, the terms and conditions of this Agreement are declared severable.

- F. Entire Agreement. This Agreement constitutes the entire agreement between the Parties relating to the transactions contemplated hereby. The Parties acknowledge they have not relied on any promise, representation or warranty, whether express or implied, not contained in this Agreement.
- G. No Partnership or Joint Venture. No partnership and/or joint venture exists between the Parties, and no partnership and/or joint venture is created by and between the Parties by virtue of this Agreement. No agent, employee, contractor, subcontractor, consultant, volunteer, or other representative of the parties shall be deemed an agent, employee, contractor, subcontractor, consultant, volunteer, or other representative of the other party.
- H. Choice of Law/ Venue. Any dispute under this Agreement or related to this Agreement shall be decided in accordance with the laws of the State of Washington. Venue for any court proceeding arising under or related to this Agreement shall be in Skagit County Superior Court.
- I. Binding Effect; No Assignments. This Agreement will be binding upon and inure to the benefit of the Parties and their respective heirs, trustees, executors, administrators, and successors. The Parties represent, covenant, and warrant they have not directly or indirectly assigned, transferred, encumbered, or purported to assign, transfer, or encumber to any person or entity any portion of any liability, claim, demand, action, cause of action, or rights herein released and discharged in this Agreement.
- J. Counterparts. This Agreement may be executed in counterparts, and when each party has signed and delivered at least one such counterpart, each counterpart shall be deemed an original, and, when taken together with other signed counterparts, shall constitute one Agreement, which shall be binding upon and effective as to all Parties.

V. Signatures

The Parties hereto have executed this Property Agreement on the dates shown below.

EXHIBIT A  
Property Descriptions:

**Wynn Family Trust Property:**

That portion of the Burlington Northern Railroad designated as reserve right-of-way for the Seattle and Northern Railroad as shown on the plat "MAP OF THE CITY OF ANACORTES, SKAGIT COUNTY, WASHINGTON", as per plat recorded in Volume 2 of Plats, page 4, records of Skagit county, Washington.

TOGETHER WITH a portion of Tract 14 of Plate No. 8 of the tide and shorelands of Section 13, Township 35 North, Range 1 East, W.M., Anacortes Harbor, all being more particularly described as follows:

Beginning at the intersection of 11<sup>th</sup> Street and "B" Avenue of said plat:  
Thence North 0°33'35" East along the Northerly projection of the centerline of "B" Avenue, a distance of 217.06 feet to the true point of beginning being an intersection with a curve having a radius point bearing North 20°46'49" West, a radial distance of 985.37 feet;  
Thence Southwesterly along the arc of said curve to the right through a central angle of 2°58'54", an arc distance of 51.28 feet; thence South 72°12'05" West, a distance of 13.20 feet to the beginning of a curve to the left having a radius of 925.36 feet; thence along the arc of said curve through a central angle of 5°04'10", an arc distance of 81.88 feet; thence North 8°56'58" West, a distance of 70.47 feet; thence North 62°14'00" East, a distance of 169.11 feet to the interaction with the Northerly projection of the centerline of "B" Avenue;  
Thence South 0°33'35" West, a distance of 98.99 feet to the true point of beginning.

Situate in the County of Skagit, State of Washington.

All of Block 242, "MAP OF THE CITY OF ANACORTES", as per plat recorded in Volume 2 of Plats, page 4, records of Skagit County, Washington, TOGETHER WITH that portion of the West Half of vacated "B" Avenue lying between the North line of Eleventh Street and the Northwestern boundary of said Block 242 extended Northeasterly, TOGETHER WITH portions of those certain strips, parcels, or tracts of land in Government Lot 5 of Section 13, Township 35 North, Range 1 East, W.M., shown and designated on the said map of the City of Anacortes as "SEATTLE AND NORTHERN RAILWAY COMPANY'S STATION GROUND", and as "RESERVED RIGHT OF WAY FOR THE SEATTLE AND NORTHERN RAILWAY, according to a certain paper in writing in escrow with John P. Hoyt, dated May 28, 1889", described as follows:

Beginning at the intersection of the centerline of "B" Avenue and Eleventh Street as shown on said Plat; thence North 0°27'11" East along the centerline of "B" Avenue a distance of 40.00 feet to the South line of said Block 242 extended Easterly, and the true point of beginning; thence North 0°37'11" East a distance of 177.32 feet to a point

on curve which lies 30 feet Southerly (and radially) from the centerline of the railroad, as now located and constructed, the radius point of said curve being North 20°49'23" West a distance of 985.37 feet from the above described "point on curve"; thence Westerly, on a curve to the right, through a central angle of 3°01'23", an arc distance of 52.01 feet; thence South 72°12'05" West, parallel with and 30 feet distance (southeastern) from the center of said railroad a distance of 13.19 feet to the beginning of a curve to the left having a radius of 925.37 feet; thence along said curve to the left through a central angle of 5°04'10", an arc distance of 81.88 feet, said point being 30 feet southerly (as measured radially) from the centerline of the railroad; thence South 9°13'41" East a distance of 128.45 feet to the point on curve on the original railroad right of way line, said curve having a radius of 7,789.44 feet the radius point of said curve being North 24°48'57" West a distance of 7,789.44 feet from the above described "point on curve"; thence Northeasterly on said curve to the left, through a central angle of 0°00'22", an arc distance of 0.82 feet, to the westerly corner of Block 242; thence South 89°24'09" East along the South line of Block 242 and said South line extended, a distance of 115.13 feet to the true point of beginning;

SUBJECT TO easement for underground truck and/or lateral sewers in favor of the City of Anacortes, a municipal corporation, recorded November 15, 1961, under Auditor's No. 614521, affecting the East eight feet (8') of the West Half of B Avenue produced northerly from the North line of 11<sup>th</sup> Street to Great Northern Railroad right of way.

### **Ortman Properties**

Ortman Family LLC, is the owner of real property legally described as:

Lots 7 through 10, Block 243, MAP OF THE CIYT OF ANACORTES, according to the Plat thereof recorded in Volume 2 of Plats, pages 4 through 7, records of Skagit County, Washington.

Together with that portion of vacated 11<sup>th</sup> Street which would attached by operation of law in accordance with City of Anacortes Ordinance No 2824.

Anacortes 1, LLC is the owner of real property legally described as follows:

That portion of those certain strips, parcels or tracts of land in Section 24 and Government Lot 5 of Section 13, Township 35 North, Range 1 East of the Willamette meridian, shown and designated on the original Plat of the City of Anacortes as "Seattle and Northern Railway Company's Station Ground," and as "Reserved right-of-way for company's right-of-way for the Seattle and Northern Railway, according to a certain paper in writing in escrow with John P. Hoyt, dated May 28, 1889," described as follows:

Commencing at the intersection of the centerline of "B" Avenue and Eleventh Street; thence North 0°37'11" East along the centerline of "B" Avenue a distance of 40.00 feet to the South line of Block 242 extended Easterly;

Thence North 0°37'11" East a distance of 177.32 feet to a point on a curve which lies 30 feet Southerly (and radially) from the centerline of the railroad, as now located and constructed, the radius point of said curve being North 20°49'23" West a distance of 985.37 feet from the above described "point on curve";

Thence Westerly, on a curve to the right, through a central angle of 3°01'28", an arc distance of 52.01 feet;

Thence South 72°12'05" West, parallel with the 30 feet distant (Southeasterly) from the center of said Railroad a distance of 13.19 feet at the beginning of a curve to the left having a radius of 925.37 feet;

Thence along said curve to the left through a central angle of 5°04'10", an arc distance of 81.88 feet, said point being 30 feet Southerly (as measured radially) from the centerline of the railroad, said point also being the true point of beginning;

Thence South 9°13'41" East a distance of 128.45 feet to the point on curve on the original Railroad right-of-way line, said curve having a radius of 7,789.44 feet, the radius point of said curve being North 24°48'57" West a distance of 7,789.44 feet from the above described "point on curve";

Thence Southwesterly along said curve to the right having a radius of 7,789.44 feet, through a central angle of 1°48'44", an arc distance of 246.37 feet to the Northwestern corner of Lot 10, Block 243, City of Anacortes, according to plat thereof recorded in Volume 2 of Plats, page 4, records of Skagit county, Washington, and the Easterly margin of "A" Avenue, according to said plat;

Thence North 0°37'11" East, along the Northerly extension of said Easterly margin of "A" Avenue, 115.00 feet to a point on a line that is parallel with and 30 feet distant Southeasterly from the centerline of said Railroad (as measured at right angles);

Thence North 58°51'30" East, along said parallel line 98.64 feet to a point of curvature in said parallel line;

Thence along the arc of said curve to the right having a radius of 925.37 feet, through a central angle of 8°16'25" an arc distance of 133.63 feet to the true point of beginning.

Together with that portion of vacated 11<sup>th</sup> Street, which would attach by operation of law in accordance with City of Anacortes Ordinance No. 2824.

Anacortes 2, LLC, is the owner of real property legally described as follows:

The West half of Lot 3 and all of Lots 4, 5, and 6, Block 243, City of Anacortes, according to the Plat recorded in Volume 2 of Plats, pages 4 through 7, records of Skagit County, Washington.

Together with that portion of vacated 11<sup>th</sup> Street which would attach by operation of law in accordance with City of Anacortes Ordinance No. 2824.

Anacortes 3, LLC, is the owner of real property legally described as follows:

Lots 1 and 2 and the East half of Lot 3, Block 243, City of Anacortes, according to the Plat recorded in Volume 2 of Plats, pages 4 through 7, records of Skagit County, Washington.

**EXHIBIT B**

**LEGAL DESCRIPTION VACATION #1**  
**TO P31488 ANACORTES 1 LLC**

That portion of Government Lot 5, Section 13, Township 35 North, Range 01 East of the Willamette Meridian, described as follows:

The West 14.05 feet of the North 1/2 of 11<sup>th</sup> lying southerly of the SEATTLE & NORTHERN RAILWAY COMPANY'S STATION GROUND and Westerly of a line projected South that is Southwest of the Southwest corner of Block 242, Plat of "MAP OF THE CITY OF ANACORTES", per plat recorded in Volume 2 of Plats, pages 4 through 7, inclusive, records of Skagit County, Washington, said line being 1.01 feet southwest on a curve to the right with the center point of a radius bearing North 24°53'07" West, 7789.44 feet and a central angle of 0°00'27".

**LEGAL DESCRIPTION VACATION #2**  
**TO P56379 WYNN FAMILY TRUST**

That portion of Government Lot 5, Section 13, Township 35 North, Range 01 East of the Willamette Meridian, described as follows:

The North 1/2 of 11<sup>th</sup> Street lying southerly of the SEATTLE & NORTHERN RAILWAY COMPANY'S STATION GROUND and Block 242, Plat of "MAP OF THE CITY OF ANACORTES", per plat recorded in Volume 2 of Plats, pages 4 through 7, inclusive, records of Skagit County, Washington and Easterly of a line projected South that is Southwest of the Southwest corner of said Block 242, said line being 1.01 feet southwest on a curve to the right with the center point of a radius bearing North 24°53'07" West, 7789.44 feet and a central angle of 0°00'27", and Westerly of a line beginning in the Southeast corner of vacated "B" Avenue according to Vacation Ordinance 684; thence South 0°33'28" East, 6.00 feet; thence South 41°59'48" West, 45.35 feet to the center line of 11<sup>th</sup> Street.

**LEGAL DESCRIPTION VACATION #3 & #4**  
**TO P56380 ANACORTES 3 LLC**

That portion of Section 24, Township 35 North, Range 01 East of the Willamette Meridian, described as follows:

That portion of the South ½ of 11<sup>th</sup> Street adjacent to and lying north of Lots 1 & 2 and the East ½ of Lot 3, Block 243, Plat of "MAP OF THE CITY OF ANACORTES", per plat recorded in Volume 2 of Plats, pages 4 through 7, inclusive, records of Skagit County, Washington and the West 10 feet of "B" Avenue within the 11<sup>th</sup> Street right-of-way.

ALSO the West 10 feet of "B" Avenue adjacent to and abutting the north 70 feet of Lot 1 of said Block 243.

**LEGAL DESCRIPTION VACATION #5**

**TO P56382 Ortman Family LLC**

That portion of Section 24, Township 35 North, Range 01 East of the Willamette Meridian, described as follows:

West 10 feet of the South 30 feet of "B" Avenue adjacent to and abutting Lot 1 of, Block 243, Plat of "MAP OF THE CITY OF ANACORTES", per plat recorded in Volume 2 of Plats, pages 4 through 7, inclusive, records of Skagit County, Washington .

**EXHIBIT C**  
**Easement Descriptions:**

**Ortman Easement**

That portion of the Burlington Northern Railroad designated as reserve right-of-way for the Seattle and Northern Railroad as shown on the Plat "Map of the City of Anacortes, Skagit County, Washington", as per plat recorded in Volume 2 of Plats, page 4, records of Skagit County Washington;

TOGETHER WITH a portion of Tract 14 of Plate No.8 of the Tide and Shorelands of Section 13, Township 35 North, Range 1 East, W.M., Anacortes Harbor, all being more particularly described as follows:

Beginning at the Southwest corner of Block 243 of said Plat; then North 0 degrees 33'46" east along a projection of the West edge of said Block, a distance of 308.10 feet to the true point of beginning; thence North 0 degrees 33'46" East, a distance of 102.32 feet; thence North 70 degrees 44'00" East, a distance of 130.63 feet; thence North 62 degrees 14'00" East, a distance of 77.28 feet; thence South 8 degrees 56'58" East, a distance of 70.47 feet to an intersection with a curve having a radius point bearing South 22 degrees 52'05" East, a radian distance of 925.36 feet; thence Westerly along the arc of said curve to the left through a central angle of 8 degrees 16'25", an arc distance of 133.62 feet; thence South 58 degrees 51'30" West a distance of 98.98 feet to the true point of beginning.

EXCEPT the South 13.5' thereof.

**Wynn Easement:**

**PORTION OF PARCEL P56379:**

That portion of the Burlington Northern Railroad designated as reserve right-of-way for the Seattle and Northern Railroad as shown on the "MAP OF THE CITY OF ANACORTES, SKAGIT COUNTY, WASHINGTON", as per plat recorded in Volume 2 of Plats, page 4, records of Skagit County, Washington.

TOGETHER WITH a portion of Tract 14 of Plate No. 8 of the tide and shoreline of Section 13, Township 35 North, Range 1 East, W.M., Anacortes Harbor, all being more particularly described as follows:

Beginning at the intersection of 11<sup>th</sup> Street and "B" Avenue of said Plat:

Thence north  $0^{\circ}33'35''$  East along the Northerly projection of the centerline of "B" Avenue, a distance of 217.06 feet to the true point of beginning being an intersection with a curve having a radius point bearing North  $20^{\circ}46'49''$  West, a radial distance of 985.37 feet:

Thence Southwesterly along the arc of said curve to the right through a central angle of  $2^{\circ}58'54''$ , an arc distance of 51.28 feet;

Thence South  $72^{\circ}12'05''$  West, a distance of 13.20 feet to the beginning of a curve to the left having a radius of 925.36 feet;

Thence along the arc of said curve through a central angle of  $5^{\circ}$  an arc distance of 81.88 feet;

Thence North  $8^{\circ}56'58''$  West, a distance of 70.47 feet;

Thence North  $62^{\circ}14'00''$  East, a distance of 169.11 feet to the intersection with the Northerly projection of the centerline of "B" Avenue;

Thence South  $0^{\circ}33'35''$  West, a distance of 98.99 feet to the true point of beginning.

EXCEPT the South 10 feet there of.

Situate in the County of Skagit, State of Washington.

## City Council Agenda Bill

**Meeting Date:** May 10, 2021

**Agenda Item:** 6.a.

**Agenda Item Title:** CDBG 2021 Annual Action Plan

**Staff Contact(s):** DON MEASAMER, Joann Stewart

**Approved for Submittal to Council by**   **Action Type**

Joann Stewart

Public Hearing

DON MEASAMER

**Item Summary:** The goals of this plan include funding supportive services to help individuals and families from becoming homeless, supporting efforts to reduce poverty, creating sustainable and healthy living accommodations for low income seniors and disabled individuals. The City Council previously elected not to utilize the administration portion of the funding and instead apply the 20% allocation to projects. The proposed funding goals being considered are listed below:

- Public Service - Anacortes Family Center - Homelessness/assist special needs populations - Create suitable living environs - \$14,395
- Low Income Senior Housing Rehabilitation – Anacortes Housing Authority Harbor House Roof Replacement - \$100,000

Section 108 Loan Program – Anacortes Family Center “The Landing” mixed use low income housing complex. The loan funding will be used to fund the costs of the pre-construction (construction drawings, architectural design) for the development of the public facility portion of the 1<sup>st</sup> floor of the complex. This will help with the costs of the construction of the early childhood learning center - \$150,000 approximately. The loan will fund the pre-construction costs of the public facilities portion (the first floor) only for the Anacortes Family Center’s construction of a mixed-use, low-income apartment complex on 26<sup>th</sup> Street in Anacortes. This will include the costs for loan origination fees, appraisal fees, architectural fees, structural design, admin and staff time for the development of the public facilities portion only and will achieve the national objective of public facilities development in a predominantly low income area. The loan amount is expected to be approximately \$150,000 and will be repaid by future CDBG annual allocations.

**Budget Impact:**

Annual Allocation from HUD - \$114,395; Section 108 Loan \$150,000 approximately; all funding is reimbursed by HUD CDBG program

**Previous Action:** Review of draft 2021 Annual Action Plan and proposed projects at [April 26, 2021](#), City Council meeting.

**Recommended Motion:** I move to accept the proposed projects and direct staff to submit the draft Action Plan to HUD no later than May 15, 2021.

**Alternative Actions:** None at this time. The Public Comment period is closed other than discussion at the final hearing on May 10, 2021.

## **Executive Summary**

### **AP-05 Executive Summary - 91.200(c), 91.220(b)**

#### **1. Introduction**

This chapter outlines the City's one-year Action Plan for 2021, which will further the goals and strategies of the Strategic Plan and is the spending plan for the City's Community Development Block Grant (CDBG) funds. The funding received will be used to accomplish the activities outlined in this plan. The allocation for this year's funding is approximately \$114,395. The proposed activities must meet the CDBG National Objectives as outlined in the introduction to the Strategic Plan and meet the public benefit standard. The Mayor of Anacortes has designated the Planning, Community & Economic Development Department responsible for the planning, development, and implementation of its CDBG Program.

#### **2. Summarize the objectives and outcomes identified in the Plan**

This could be a restatement of items or a table listed elsewhere in the plan or a reference to another location. It may also contain any essential items from the housing and homeless needs assessment, the housing market analysis, or the strategic plan.

The goals of this plan include funding supportive services to help individuals and families from becoming homeless, supporting efforts to reduce poverty, constructing public facility upgrades to provide suitable living environments through the removal of architectural barriers to accommodate mobility restricted individuals. The City Council has previously elected not to utilize the administration portion of the funding and instead apply the 20% allocation to projects. The proposed funding goals being considered are listed below:

- Public Service - Anacortes Family Center - Homelessness/assist special needs populations - Create suitable living environs - \$14,395
- Low-income Senior Housing Rehabilitation – Anacortes Housing Authority Harbor House Roof Replacement - \$100,000
- Section 108 Loan Program – Anacortes Family Center “The Landing” mixed use low-income housing complex. The loan funding will be used to fund the costs of the pre-construction (construction drawings, architectural design) for the development of the public facility portion of the 1<sup>st</sup> floor of the complex. This will help with the costs of the construction of the early childhood learning center - \$150,000 approximately.

As listed above, the City expects to utilize a Section 108 loan program through HUD. This program provides communities with a source of financing for economic development, housing rehabilitation, public facilities, and large-scale physical development projects. It allows them to transform a small

portion of their CDBG funds into federally guaranteed loans large enough to pursue physical and economic revitalization projects that can renew entire neighborhoods. As a CDBG entitlement, the City is eligible to apply for this type of funding.

This program provides the City with the opportunity to borrow up to 5 times the annual allocation. This year's funding amount is \$114,395 which allows the City to borrow a maximum of \$571,975. Principal security includes a pledge of the future CDBG funds along with additional security and the interest is variable.

The loan will fund the pre-construction costs of the public facilities portion (the first floor) only for the Anacortes Family Center's construction of a mixed-use, low-income apartment complex on 26<sup>th</sup> Street in Anacortes. This will include the costs for loan origination fees, appraisal fees, architectural fees, structural design, admin and staff time for the development of the public facilities portion only and will achieve the national objective of public facilities development in a predominantly low-income area. The loan amount is expected to be approximately \$150,000 and will be repaid by future CDBG annual allocations.

### **3. Evaluation of past performance**

This is an evaluation of past performance that helped lead the grantee to choose its goals or projects.

In reviewing activities accomplished with its federal funding from previous years, the City of Anacortes advanced its goals of improving conditions, creating better housing resources and opportunities, and assisting human service organizations in providing effective support services to priority low-income and homeless populations. The projects selected are based on consultation with local agencies and in response to the area's countywide Continuum of Care Plan. The Anacortes Family Center, recipient of the full public services portion of the annual CDBG, provided that approximately 84% of the 62 households (175 individuals - 105 of which were children) in their program during 2019 successfully graduated from the Family Center program and entered permanent, safe housing with jobs and incomes to support their new lives.

The 2020 allocation was redirected from the original purpose of funding the Housing Authority roof replacement project to assist businesses within Anacortes with economic support. This provided financial assistance to local small businesses (no more than 30 employees) to help reduce the losses associated with the Covid restrictions. To date, the City has provided 18 businesses with a total of 84 employees with this funding to help keep their doors open and their employees in jobs.

### **4. Summary of Citizen Participation Process and consultation process**

Summary from citizen participation section of plan.

In deciding the 2021 program year allocations, the City of Anacortes worked with community leaders and the City Council Housing Affordability & Community Services committee to determine the proposed projects. The City held a 30 day public comment period in accordance with the HUD requirements. The City held 2 virtual public hearings on April 26, 2021 and May 10, 2021). Notice was published on the website and in the local newspaper and encouraged public comment in conjunction with the CDBG program. The notice for the 30 day comment period and meetings was posted on the City's website on March 26, 2021 and published in the local newspaper on March 31, 2021. The public comment period began on April 5, 2021 and ended May 5, 2021.

## **5. Summary of public comments**

This could be a brief narrative summary or reference an attached document from the Citizen Participation section of the Con Plan.

The City did not receive any public comments on the development of the 2021 Annual Action Plan.

## **6. Summary of comments or views not accepted and the reasons for not accepting them**

The City did not reject any views or comments on the development of this Action Plan.

## **7. Summary**

The overall goal of the community planning and development programs available from the City of Anacortes with CDBG funding is to assist in the development of affordable housing for low and moderately low-income households, reduce poverty in Anacortes, assist in creating better living conditions for low-income households and provide funding to assist human service agencies serving low-income populations. A review of the projects and activities implemented in program years 2019 and 2020 demonstrates that the City is making progress in fulfilling its goals. The City intends to continue to work closely with HUD staff to improve performance in timely implementation of identified community development strategies and CDBG administrative activities. The City did not hinder Consolidated Plan implementation by action or willful inaction.

## PR-05 Lead & Responsible Agencies - 91.200(b)

### 1. Agency/entity responsible for preparing/administering the Consolidated Plan

The following are the agencies/entities responsible for preparing the Consolidated Plan and those responsible for administration of each grant program and funding source.

| Agency Role        | Name      | Department/Agency                          |
|--------------------|-----------|--------------------------------------------|
| CDBG Administrator | ANACORTES | Planning, Community & Economic Development |

Table 1 – Responsible Agencies

### Narrative

The city of Anacortes is a member of the Skagit County Home Consortium which is comprised of 20 municipalities. Anacortes is a participating CDBG entitlement jurisdiction that administers its own CDBG programs. The Mayor of Anacortes has designated the Planning, Community & Economic Development Department to perform the planning, development, and implementation of the Anacortes CDBG program.

## **AP-10 Consultation - 91.100, 91.200(b), 91.215(l)**

### **1. Introduction**

The City performed an extensive outreach program to consult and coordinate with non-profit agencies, affordable housing providers, government agencies and other entities.

**Provide a concise summary of the jurisdiction's activities to enhance coordination between public and assisted housing providers and private and governmental health, mental health and service agencies (91.215(l)).**

The City held two public hearings to obtain input from all citizens of the community. The first public hearing was April 26, 2021. This meeting provided an opportunity to discuss the objectives of the Action Plan and proposed projects for 2021. The next meeting was held on May 10, 2021.

The City sent inquiries to various organizations and individuals to obtain current information on pressing needs within the community. Input was received from Community Action Agency of Skagit County, the Anacortes Community Health Council (comprised of representatives of churches, private organizations, social service agencies, city departments and community groups who provide support for Anacortes citizens), the Anacortes Family Center, and the City of Anacortes Housing Affordability & Community Services Committee.

The Anacortes Community Health Council member agencies include: Anacortes Family Center; Anacortes Senior Activity Center; Island Hospital Community Health Resource Center; The Salvation Army; St. Vincent de Paul; Anacortes 100 Food Bank; Christ Episcopal Church; Anacortes United Methodist Church; Anacortes/San Juan Island Chapter of the American Red Cross; Anacortes First Baptist Church; Anacortes Christian Church; Anacortes Police Department; Skagit Senior Information and Assistance; Anacortes Noon Kiwanis Club; Anacortes Boys and Girls Club; Skagit County Youth and Family Services; Pilgrim Congregational Church; Anacortes Housing Authority; Christ the King Community Church; Westminster Presbyterian Church/Dinner at the Brick.

**Describe coordination with the Continuum of Care and efforts to address the needs of homeless persons (particularly chronically homeless individuals and families, families with children, veterans, and unaccompanied youth) and persons at risk of homelessness.**

The City incorporates the Skagit County Continuum of Care plans which prioritizes the use of HOME and CDBG funds toward the goals of ending homelessness.

**Describe consultation with the Continuum(s) of Care that serves the jurisdiction's area in determining how to allocate ESG funds, develop performance standards for and evaluate**

**outcomes of projects and activities assisted by ESG funds, and develop funding, policies and procedures for the operation and administration of HMIS**

The City has coordinated with Skagit County Department of Public Health & Community Services, Skagit County Coalition to End Homelessness, and Community Action through the HOME Consortium efforts. These organizations are responsible for using ESG funds and for administering HMIS (Homeless Management Information System) for service providers operating in the Consortium region. Their goals, strategies, activities, and outcomes have been incorporated in the Consolidated Plan.

**2. Agencies, groups, organizations and others who participated in the process and consultations**

|   | <b>Briefly describe how the Agency/Group/Organization was consulted. What are the anticipated outcomes of the consultation or areas for improved coordination?</b> | Monthly meetings with departments/local groups to determine strategies to address lack of affordable housing within community, job security                                                         |

#### Identify any Agency Types not consulted and provide rationale for not consulting

All major community agencies were consulted either directly or indirectly. The local CBDO, Home Trust of Skagit, actively works with the multi-county/city HOME Consortium. This agency utilizes HOME resources to support their housing efforts.

### Other local/regional/state/federal planning efforts considered when preparing the Plan

| Name of Plan                                  | Lead Organization                | How do the goals of your Strategic Plan overlap with the goals of each plan?                                      |
|-----------------------------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Continuum of Care                             | Skagit County Community Services | The Strategic Plan has adopted the major strategies of the 10 year plan                                           |
| 2016 Comprehensive Plan update                | City of Anacortes                | Creating a better, coordinated strategy for LMI affordable homes and related issues                               |
| North/West Basin Concept Plan                 | Port of Anacortes                | Creating a better, coordinated strategy for public facilities improvements                                        |
| 2019 Affordable Housing Strategic Plan        | City of Anacortes                | Creating a coordinated strategy for the development of affordable homes & community services within the community |
| Skagit County Natural Hazards Mitigation Plan | Skagit County                    | Creating a coordinated strategy for the community in the event of a natural or man-made disaster                  |
| Fiber Optics Installation                     | City of Anacortes                | Creating opportunities to help low-income residents connect to broadband services to narrow the digital divide    |
|                                               |                                  |                                                                                                                   |

**Table 3 - Other local / regional / federal planning efforts**

### Narrative

The City coordinated efforts with the County, the Anacortes Housing Authority, the Anacortes Family Center, the Anacortes Community Health Council and the City of Anacortes Affordable Housing & Community Services Committee to share concerns, determine the needs and routes to follow to address the needs.

## AP-12 Participation - 91.401, 91.105, 91.200(c)

### 1. Summary of citizen participation process/Efforts made to broaden citizen participation Summarize citizen participation process and how it impacted goal-setting

In deciding the 2021 program year funding allocations, the City of Anacortes conducted two public hearings (April 26, 2021 and May 10, 2021) and encouraged public comment on the development of the City's CDBG Action Plan. The notice for the public hearings was advertised in the Anacortes American and posted on the City's website. The notice for the 30 day comment period and meetings were posted on the City's CDBG website on March 26, 2021 and published on March 31 2021. The public comment period began on April 5 and ended May 5, 2021.

In addition to the hearings, the City also consulted with local housing and human service providers to obtain input on the Action Plan.

The impact this had on the goal setting was the need for more affordable housing and living wage jobs. The City plans to work toward achieving these goals utilizing CDBG funding and other funding sources.

#### Citizen Participation Outreach

| Sort Order | Mode of Outreach | Target of Outreach                                                                                           | Summary of response/attendance    | Summary of comments received | Summary of comments not accepted and reasons   | URL (If applicable) |

| 1          | Public Hearing   | Non-targeted/broad community outreach<br><br>Small business owners; residents of Public and Assisted Housing | No public comments were presented |                              | There were no comments that were not accepted. |                     |

Table 4 – Citizen Participation Outreach

## Expected Resources

### AP-15 Expected Resources - 91.420(b), 91.220(c)(1,2)

#### Introduction

The City expects to utilize the entire allocation of \$114,395 for program year 2021. This funding will advance the goals of this plan to improve living conditions and fund supportive services to help individuals and families from becoming homeless and support efforts to reduce poverty.

#### Anticipated Resources

|         |                                            |                                       | Annual Allocation: \$            | Program Income: \$ | Prior Year Resources: \$ | Total: \$ |                                                   |                                                                                                                                                                                                                                                                           |
| CDBG    | Public - federal                           | Public Housing Rehab; Public Services | \$114,395                        | 0                  | \$0                      | \$114,395 | 0                                                 | The City will utilize the entire allocation for program year 2021. The City expects to use \$100,000 for the roof replacement at the Housing Authority Harbor House, a low-income apartment complex for seniors. The remaining amount will be applied to public services. |
| CDBG    | Public – federal, Section 108 Loan Program | Public Facilities                     | \$150,000                        |                    |                          |           | 0                                                 | The City will utilize a Section 108 loan. The loan is generated through the annual allocation and the City can utilize up to 5 years of annual allocations. The City is allowed at total loan amount of \$571,975                                                         |

Table 5 - Expected Resources – Priority Table

**Explain how federal funds will leverage those additional resources (private, state and local funds), including a description of how**

### **matching requirements will be satisfied**

Federal funds the City receives through the Community Development Block Grant (CDBG) are used to leverage other federal, state, local and private resources to meet housing and community development needs. While matching funds are not currently required for the City's CDBG program, the City anticipates that most major projects will be funded primarily through non-CDBG resources. On February 11, 2020, the citizens of Anacortes approved a 1/10<sup>th</sup> of 1% sales tax increase to fund affordable and supportive housing within the community. This, along with a corresponding sales tax credit from the state, will contribute up to an estimated \$17 million over 20 years to development of affordable housing. These funds will be used in the development of the AFC mixed use, low-income apartment complex.

### **If appropriate, describe publicly owned land or property located within the jurisdiction that may be used to address the needs identified in the plan**

The City identified core areas where infrastructure improvements would allow better access for all individuals and in particular, disabled residents and visitors. Community participation on the 2016 Comprehensive Plan update also identified areas in the core downtown that are being considered for development of a central hub. Proposals include residential development, retail, public services, restaurant, grocery, and entertainment establishments that will be easily and safely accessible.

### **Discussion**

The 2016 Comprehensive Plan provides a unique vision to create a cohesive, well-laid out community with affordable housing and pedestrian mobility key factors in determining the paths to the central hub as described above. Zoning regulations are now in place that encourage development of multi-family mixed-use complexes, increased density in neighborhoods previously zoned single detached homes, and allow easier routes to access services other than vehicle use (more bicycle lanes and less space needed for parking). This will help create more affordable living space within the central hub of downtown.

In addition, the City has received an Opportunity Zone designation. City Planning staff is working to encourage development within this zone that will accommodate and enhance opportunities for the lower income population residing in this OZ as well as throughout the entire community.

## AP-35 Projects - 91.420, 91.220(d)

### Introduction

The projects chosen are based on HUD criteria that the activity meet at least one of the national objectives (benefit to low and moderately low-income persons, aid in the prevention or elimination of slums or blight, and meet a need having a particular urgency) and they meet the criteria established in the City's Strategic Plan. The City determined that the public services funding be provided to the Anacortes Family Shelter as the Center meets a need of particular urgency by assisting families and women who would otherwise end up living on the streets.

The Harbor House low-income senior and disabled housing provides homes for 50 households. The roof on this complex has gone well beyond its maximum lifespan and requires replacement. This will benefit 60 low-income seniors and disabled individuals living in the 50 unit complex with decent affordable housing.

The support of the AFC's early childhood learning center in the public facilities portion of The Landing project will help families get a head start on childhood learning so they are well prepared to enter the education system and their future. The value of early childhood education is key to developing a good foundation on which to build as the child goes through school; early childhood learning provides academics as well as helps the child develop a good sense of self and family and an understanding that their actions can make a better world. This is a great investment to help families become successful in the future.

| # | Project Name                                                  |
|---|---------------------------------------------------------------|
| 1 | Public Services – supportive services costs for clients       |
| 2 | Public Housing Rehab – Modernization                          |
| 3 | Public Facilities development under 570.703(l) & 570.201(c) - |

Table 7 – Project Information

### Describe the reasons for allocation priorities and any obstacles to addressing underserved needs

The City established priorities for allocating resources and long-range strategies following a careful assessment of the needs and demographics of the community. A clear priority identified in the analysis is a response to the needs of low to moderately low-income families and individuals within the City for safe and affordable housing and basic services such as medical, dental, and home energy assistance. Families and individuals in crisis situations need significant services and housing to be able to reach self-sufficiency. Included in this population are the homeless and others with special needs that generally are either priced out of housing or are unable to maintain stable housing.

Improving conditions, creating new housing resources and opportunities, retaining jobs, and reducing housing costs to affordable levels represent major means of responding to the needs of the targeted

population. The strategies and objectives outlined in the 2018-2022 Strategic Plan reflect these priorities and outline activities designed to alleviate these needs.

The primary basis for allocation of resources is to serve the needs of the low and moderately low-income households. Consolidated Plan strategies developed through the community planning process reflect that a significant amount of funds are targeted to projects that benefit the low to moderately low-income households. The public services portion provides services and resources to the households in need while the remaining resources are directed to projects that provide safe and stable transitional and permanent housing for families and individuals in need.

A major obstacle to address underserved needs is lack of funding.

|   | <b>Estimate the number and type of families that will benefit from the proposed activities</b> | The Anacortes Family Center estimates service for approximately 200 individuals consisting of families with children and single women. The program provides intensive self-sufficiency based services and shelter for homeless single women, children and families with children in crisis, most often due to domestic violence. Approximately 60% of the clients will be children. Nearly all of the clients have complex issues involving generational violence, poverty and mental illness |

|   |                                                                                                |                                                                                                                                                                                                                                                                                                                                                  |
| 3 | <b>Project Name</b>                                                                            | Anacortes Family Center – The Landing                                                                                                                                                                                                                                                                                                            |
|   | <b>Target Area</b>                                                                             | Census Tract 940500                                                                                                                                                                                                                                                                                                                              |
|   | <b>Goals Supported</b>                                                                         | Supporting development of public neighborhood facilities in a low to moderately low-income area                                                                                                                                                                                                                                                  |
|   | <b>Needs Addressed</b>                                                                         | Serving a predominantly low-income area with early childhood learning center                                                                                                                                                                                                                                                                     |
|   | <b>Funding</b>                                                                                 | CDBG Section 108 Loan – CDBG \$150,000                                                                                                                                                                                                                                                                                                           |
|   | <b>Description</b>                                                                             | Provide funding to assist the development of an early childhood learning center. Funding will be limited to soft costs of public facilities only development, i.e., architectural and construction design, project development analysis, administration of design development                                                                    |
|   | <b>Target Date</b>                                                                             | 6/30/22                                                                                                                                                                                                                                                                                                                                          |
|   | <b>Estimate the number and type of families that will benefit from the proposed activities</b> | There are approximately 21,576 as of 2019 (US Census), this neighborhood comprises approximately 2,465 low to moderately low-income individuals. This facility will provide services to the entire community.                                                                                                                                    |
|   | <b>Location Description</b>                                                                    | 1019 26 <sup>th</sup> Street, Anacortes                                                                                                                                                                                                                                                                                                          |
|   | <b>Planned Activities</b>                                                                      | Section 108 loan to provide funding for soft costs for development of public facility (early childhood learning center) in a mixed use, low-income apartment, public facility complex. The funding will be repaid over a 2-3 year period with CDBG annual allocations to assist in the development of a much needed low-income apartment complex |

## **AP-50 Geographic Distribution - 91.420, 91.220(f)**

### **Description of the geographic areas of the entitlement (including areas of low-income and minority concentration) where assistance will be directed**

Anacortes is located on Fidalgo Island in Skagit County with 12.5 miles of saltwater shoreline, four freshwater lakes, and 3000 plus acres of city-owned forestlands and city-owned parks. Anacortes is approximately 20 miles from the county seat in Mount Vernon, Washington. A majority of public services to Skagit County citizens are available primarily in the Mount Vernon area.

The current population of Anacortes is approximately 17,283 citizens (US 2018 Census estimates). Anacortes has two areas with a concentration of moderately low to low-income households, Census Tracts 940500 and 940600 with 64% LMI households. The overall low, to moderately low, income households in Anacortes is approximately 34%.

While Anacortes has two census tracts with the highest concentration of persons living below the poverty level, there are smaller concentrations of low-income households interspersed throughout the City. The City establishes priorities for allocating resources and long-range strategies following a careful assessment of the needs and demographics of the community. A clear priority identified in the analysis is a response to the needs of low to moderately low-income families and individuals within the City for safe and affordable housing and basic services such as medical, dental and home energy assistance. Families and individuals in crisis situations need significant services and housing to be able to reach self-sufficiency. Included in this population are the homeless and others with special needs who are generally either priced out of housing or are unable to maintain stable housing.

In addition, the City has been designated an Opportunity Zone, a portion of which lies within these census tracts. City Planning staff is working to encourage development within this zone that will accommodate and enhance opportunities for the lower income population within this zone as well as throughout the entire community.

Improving conditions, creating new housing resources and opportunities, and reducing housing costs to affordable levels represent major means of responding to the needs of the targeted population. The strategies and objectives listed in the Strategic Plan reflect these priorities and outline activities designed to alleviate these needs.

The primary basis for allocation of resources is to serve the needs of the low and moderately low-income households. Consolidated Plan strategies developed through the community planning process reflect that a significant amount of funds are targeted to projects that benefit the low to moderately low-income households. The public services portion is allocated to services that provide multiple benefits to households in dire situations and the remaining resources are directed to projects that provide safe and stable environments, transitional and permanent housing for families and individuals in

need.

### **Geographic Distribution**

| <b>Target Area</b>     | <b>Percentage of Funds</b> |
|------------------------|----------------------------|
| Tracts 940600 & 940500 | 100%                       |

**Table 8 - Geographic Distribution**

### **Rationale for the priorities for allocating investments geographically**

These areas contain the highest concentration of low to moderately low households. Most small businesses are also located in these areas.

### **Discussion**

This is where a majority of the small businesses are located, and the projects put forth for this year's funding are located in this area. This area is also situated between Highway 20 and the downtown business core and is adjacent to the marine industrial zoning where many jobs and recreation opportunities are located.

## **AP-75 Barriers to affordable housing -91.420, 91.220(j)**

### **Introduction**

The City of Anacortes is committed to promoting safe, affordable housing and reducing homelessness through the City's funding, partnership, and policy efforts.

The City of Anacortes developed an affordable housing action plan to create strategies to work toward the development of affordable housing within our community. The Strategic Plan sets forth the goals, strategies, and action items to guide the City in implementing its affordable housing policy and ultimately reduce the barriers to affordable housing.

### **Actions it planned to remove or ameliorate the negative effects of public policies that serve as barriers to affordable housing such as land use controls, tax policies affecting land, zoning ordinances, building codes, fees and charges, growth limitations, and policies affecting the return on residential investment**

Actions planned to remove or ameliorate the negative effects of public policies that serve as barriers to affordable housing include the current amendments to the City's Development Regulations:

- Simplifying standards for accessory dwelling units (ADUs) to encourage production (increasing housing supply for renters and income for homeowners);
- Encouraging small-lot single family development with a variety of lot design options (which may have lower purchase prices compared to typical large lot homes);
- Explicitly allowing cottage housing in most zones as a small-scale detached living option;
- Explicitly allowing townhouses as a small-scale attached living option;
- Explicitly defining duplex and triplex as attached living options and allowing a variety of configurations on a single site;
- Providing design standards to these new housing types to ensure livability and neighborhood compatibility;
- Providing flexibility for landscaping and lot coverage standards for multifamily and townhouse development in high-density zones to

increase their economic feasibility;

- Explicitly allowing live-work development to support home-based business owners;
- Expanding allowance of multifamily development to the MS zone and MMU zone (previously CM and CM1);
- Raising base height limits in the CBD and C zones to increase residential (and non-residential) development capacity;
- Establishing a new height bonus for the R4 zone related to small and/or affordable units;
- Adjusting parking requirements for multifamily uses to reduce the costs of construction (often passed on to tenants);
- Providing new bike parking standards to support residents who cannot afford or choose not to own a car;
- Providing new standards for group living developments to encourage their development and support seniors and people with disabilities who are often on fixed incomes;
- Updating and streamlining permitting and processing provisions to shorten development timelines and increase predictability for builders.
- Waivers and reductions in impact fees and general facilities charges for new units that will be reserved for specified lower income levels.

## Discussion

The City is continuing efforts to develop incentives to creative affordable housing. An example of these efforts include the AFC multi-family apartment complex (20 units) built within a single family housing zone. The conditions for this development include the complex must remain affordable for 50 years, all rental units developed must be affordable to and occupied by households with an income of 50 percent or less of the area median income (determined by HUD) as adjusted by family size for Skagit County. The project applicant was also able to request a waiver or exemption for the requirements to pay impact fees for traffic, parks and fire services, permit application fees and general facilities charges for sewer, water, and stormwater. This project was completed in 2019. The 20 apartments were filled immediately with families and there is a current wait list of approximately 10 families.

## **AP-85 Other Actions - 91.420, 91.220(k)**

### **Introduction**

Because the City of Anacortes's annual CDBG grant is minimal, it is difficult to use CDBG for many other purposes than those already identified. However, the City does intend to invest other resources and effort toward the following actions: implementing a human services strategic plan to help low-income individuals and families, establishing a community services center to provide services to low-income residents, developing strategies to assist the chronically homeless with shelter. The City is actively engaged in reviewing and developing strategies to assist the most vulnerable in our community.

The City received an Opportunity Zone designation that encompasses portions of the low to moderately low census tracts. The City is working to encourage development opportunities that will accommodate and enhance opportunities for the lower income population within this zone as well as throughout the entire community. The City has been working with HUD to determine opportunities that will encourage investors in the new Opportunity Zone.

The City continues to focus on assistance to small businesses within the community that face imminent shut down due to the Covid-19 pandemic. To date, the city has used CDBG and CDBG-CV funding to assist small businesses such as restaurants and retail spaces and helped keep them from closing and losing jobs. With the use of CDBG and CDBG-CV funding, the city has provided 18 businesses with a total of 84 employees with funding to help during the pandemic shutdowns. With CDBG assistance, these businesses will continue operating and retain their valuable employees. This will help lessen the burden of people facing unemployment when the restrictions are lifted in response to the pandemic.

### **Actions planned to address obstacles to meeting underserved needs**

The City, through the appointment of the Housing Affordability & Community Services Committee ("HACS"), a City Council committee, established a strategic plan to outline what the needs are and how to address those needs to eliminate the barriers to attaining affordable housing. This plan coordinates the goals of the 2016 Comprehensive Plan with incentives to develop affordable housing and provides a beginning for the City to create a more equitable and healthy community. The City also provides information to housing loan lenders, property managers, and the public about fair housing laws and includes current state and federal information with links to this information on its Planning, Community & Economic Development CDBG website (<https://www.anacorteswa.gov/181/Fair-Housing>). The City will work in collaboration with the County and the Anacortes Housing Authority in developing fair housing guidelines according to the Affirmatively Furthering Fair Housing rule. The AFFH rule provides a new approach for planning and implementing locally developed housing goals, actions and strategies to increase choice, mobility, preservation, community revitalization and other collaborative or outreach efforts designed to reduce disparities in access to opportunity and improve fair housing outcomes. This will assist in meeting our statutory obligation to affirmatively further fair housing as required by the Fair

Housing Act and will be an immense help for the City in addressing underserved needs.

### **Actions planned to foster and maintain affordable housing**

The City will work in partnership with the Anacortes Housing Authority to secure the resources necessary to rehabilitate the various HA complexes, an important low-income housing resource in Anacortes. The City will also work with the Housing Authority to promote development of more complexes to accommodate the growing wait list for affordable housing. The City appointed HACS Committee will continue to collaborate efforts to work on strategies to eliminate barriers to affordable housing and services within the City. The City is also working to encourage development of affordable housing in the recently designated Opportunity Zone in Anacortes.

In support of new low-income housing developments, the City will secure additional funding outside of the annual allocation through the CDBG Section 108 Loan program to help reduce the costs of the development of the AFC's The Landing. The loan will help cover the soft costs of the development of the public facilities portion of the project which will help reduce some of the cost of a project of this scope. This will ultimately provide 21 homes for low to moderately low and disabled individuals.

### **Actions planned to reduce lead-based paint hazards**

Code enforcement will address any and all lead-based paint issues that may arise; additionally, the City will include lead based paint hazard information in community education and outreach.

### **Actions planned to reduce the number of poverty-level families**

The Public Services funding to the Anacortes Family Center provides intensive case management and life skills education to assist the households with gaining the skills and resources needed to become fully self-sufficient. The outlook of the community through the work on the 2016 Comprehensive Plan promises to promote more living wage jobs and create a community that would support lower priced housing. This will be accomplished through zoning changes and building incentives which are now included in the Anacortes Municipal Code.

The support of the AFC's early childhood learning center in the public facilities portion of The Landing project will help families get a head start on childhood learning so they are well prepared to enter the education system and their future. The value of early childhood education is key to developing a good foundation on which to build as the child goes through school; early childhood learning provides academics as well as helps the child develop a good sense of self and family and an understanding that their actions can make a better world. This is a great investment to help families become successful in

the future.

### **Actions planned to develop institutional structure**

The City is a partner with adjacent and regional jurisdictions in a regional HOME Consortium. The regional HOME Consortium will enhance the resource base for developing more affordable housing and for addressing institutional barriers to creating more affordable housing.

### **Actions planned to enhance coordination between public and private housing and social service agencies**

The City will support the efforts of the Anacortes Community Health Council and participate regularly in their multi-agency meetings. Active participation in the Council will improve the coordination of the City's Consolidated Plan goals and the efforts to reduce instability in the lower income community. The Housing Affordability & Community Services committee will work with the public and private housing and social service agencies to develop a strategy to eliminate barriers to affordable housing and services. The HACS Committee completed the Affordable Housing Strategic Plan in 2017 <https://www.anacorteswa.gov/550/Housing-Affordability-Committee> that is designed to provide pathways to development of affordable housing within our community. The City is also very committed to working with agencies to develop a community services center to help people find basic services at affordable rates. The HACS Committee is now working on a human services strategic plan to address the lack of services available to the lower income community as well as updating the affordable housing strategic plan. The HACS committee continues working on the plan to keep it current.

### **Discussion**

Funding continues to be the main obstacle to meeting underserved need. Obstacles include lack of sufficient financial resources to address large projects such as permanent housing and shelters. The limit on the public services prohibits the City from adequately providing a greater service to households in need. In addition, not knowing how to access services or not knowing where they are located is a barrier to anyone looking for specific services; the HACS Committee expects to eliminate those issues by providing a one stop shopping for services within the City.

## Program Specific Requirements

### AP-90 Program Specific Requirements - 91.420, 91.220(I)(1,2,4)

#### Introduction

The primary basis for allocation of resources is to serve the needs of the low and moderately low-income households. The 2021 Action Plan allocates the majority of the funding to projects that benefit the low to moderately low-income households. The public services portion provides services and resources to the households in need while the remaining resources fund projects that provide better access to services or improved living conditions for individuals and families in need.

#### Community Development Block Grant Program (CDBG)

##### Reference 24 CFR 91.220(I)(1)

Projects planned with all CDBG funds expected to be available during the year are identified in the Projects Table. The following identifies program income that is available for use that is included in projects to be carried out.

The City typically does not receive Program Income.

|                                                                                                                                                                                                |                  |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| 1. The total amount of program income that will have been received before the start of the next program year and that has not yet been reprogrammed                                            | 0                |
| 2. The amount of proceeds from section 108 loan guarantees that will be used during the year to address the priority needs and specific objectives identified in the grantee's strategic plan. | \$150,000        |
| 3. The amount of surplus funds from urban renewal settlements                                                                                                                                  | 0                |
| 4. The amount of any grant funds returned to the line of credit for which the planned use has not been included in a prior statement or plan                                                   | 0                |
| 5. The amount of income from float-funded activities                                                                                                                                           | 0                |
| <b>Total Program Income:</b>                                                                                                                                                                   | <b>\$150,000</b> |

#### Other CDBG Requirements

|                                                                                                                                                                                                                                                                                                                                                                                 |         |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 1. The amount of urgent need activities                                                                                                                                                                                                                                                                                                                                         | 0       |
| 2. The estimated percentage of CDBG funds for activities that benefit persons of low and moderate income. Overall Benefit - A consecutive period of one, two or three years may be used to determine that a minimum overall benefit of 70% of CDBG funds is used to benefit persons of low and moderate income. Specify the years covered that include this Annual Action Plan. | 100.00% |

#### Discussion

100% of the 2021 funding will be allocated to benefit low to moderately low-income persons.

DRAFT

## City Council Agenda Bill

**Meeting Date:** May 10, 2021

**Agenda Item:** 6.b.

**Agenda Item Title:** Continued Public Hearing: Critical Area Regulations Draft 3

**Staff Contact(s):** TESS COOPER

| <b><u>Approved for Submittal to Council by</u></b> | <b><u>Action Type</u></b> |
|----------------------------------------------------|---------------------------|
| DON MEASAMER                                       | Public Hearing            |
| LIBBY GRAGE                                        |                           |

**Item Summary:** The proposed non-project legislative action is to amend the Critical Area regulations in accordance with the Growth Management Act requirements. The critical areas ordinance regulates certain activities and development in and near wetlands, streams, fish & wildlife habitat conservation areas, geologically hazardous areas, frequently flooded areas, and critical aquifer recharge areas. The draft includes updates in accordance with state law and best available science, reorganization, and functional changes to certain requirements.

**Budget Impact:**  
N/A

**Previous Action:** Public Hearing opened on [April 19](#), continued on [May 3](#), and had been left open to the present meeting.

**Recommended Motion:** N/A - Discussion

**Alternative Actions:**

# DRAFT Ordinance No. \_\_\_\_

## An Ordinance adopting, repealing, and amending AMC Chapter 19.70 and Chapter 17.70 relating to critical areas regulations.

Whereas \_\_\_\_\_;

Whereas \_\_\_\_\_;

Whereas \_\_\_\_\_;

Whereas \_\_\_\_\_;

**Whereas** RCW 36.70A.170 and RCW 36.70A.172 provide that the City must designate critical areas and include the best available science in developing policies and development regulations to protect the functions and values of critical areas;

**Whereas** RCW 36.70A.130 requires continuing review, evaluation and periodic update of development regulations, including critical areas regulations,

**Whereas**

**Now, therefore, the City Council of the City of Anacortes does ordain as follows:**

Section 1. The Anacortes Municipal Code is amended as shown in Attachment A.

Section 2. Consistent with RCW 35A.12.130, this ordinance takes effect five days after passage and publication.

**PASSED and APPROVED** this \_\_\_\_ day of \_\_\_\_\_, **2021**.

**CITY OF ANACORTES:**

\_\_\_\_\_  
Laurie Gere, Mayor

**Attest:**

\_\_\_\_\_  
Steve Hoglund, City Clerk-Treasurer

Approved as to Form:

\_\_\_\_\_  
Darcy Swetnam, City Attorney

## Attachment A Amendments to the Anacortes Municipal Code

[12.18 ACFL Management Section added.](#)

Chapter 17.70 Critical Areas Regulations are repealed except that .....

Recodify Article II. – Frequently Flooded Areas (FEMA Approved), AMC 17.70.020 through AMC 17.70.070 to Chapter 19.74 and retitle “Floodplain Management”.

[Table 19.20.030-1 Permit Processes added.](#)

## DIVISION 7 – ENVIRONMENT

### CHAPTER 19.70 CRITICAL AREAS

#### INTRODUCTION: GENERAL PROVISIONS

##### 19.70.010 Purpose.

- A. The purpose of this chapter is to designate critical areas and to establish standards for the protection of their functions and values, in compliance with the provisions of the Washington State Growth Management Act of 1990 (Ch. 36.70A RCW), and consistent with the goals and policies of the Anacortes Comprehensive Plan.
- B. By identifying and regulating development and alterations to critical areas and their buffers, this chapter seeks to accomplish the following goals:
  - 1. Protect members of the public and public resources and facilities from injury, loss of life, or property damage due to landslides and steep slope failures, erosion, seismic events, or flooding;
  - 2. Protect, maintain and restore healthy, functioning ecosystems through the protection of unique, fragile, and valuable elements of the environment, including, but not limited to ground and surface waters, wetlands, and fish and wildlife and their habitats, and to conserve the biodiversity of plant and animal species;
  - 3. Direct activities not dependent on critical area resources to less environmentally sensitive sites and mitigate unavoidable impacts to critical areas by regulating alterations in and adjacent to critical areas;
  - 4. Prevent cumulative adverse environmental impacts to water quality, wetlands, and fish and wildlife habitat, and the overall net loss of wetlands, frequently flooded areas, and habitat conservation areas;
  - 5. Alert owners, potential purchasers, real estate agents, appraisers, lenders, builders, developers and other members of the public to natural conditions that pose a hazard or may otherwise limit development;
  - 6. Serve as a basis for exercise of the City's substantive authority under the State Environmental Policy Act (SEPA).
- C. The regulations of this Chapter are intended to protect critical areas in accordance with the Growth Management Act, through the application of best available science, as determined according to [WAC 365-195-900](#) through [365-195-925](#), and in consultation with state and federal agencies and other qualified professionals.

- D. This Chapter is intended to be administered with limited flexibility and attention to site-specific characteristics. It is not the intent of this Chapter to make a parcel of property unusable by denying its owner reasonable economic use of the property, or to prevent the provision of public facilities and services necessary to support existing development and that planned for by the community without decreasing current service levels below minimum standards.
- E. The City's enactment or enforcement of this Chapter must not be construed for the benefit of any individual person or group of persons other than the general public.

#### 19.70.015 Applicability.

~~A.~~ Unless explicitly exempted, the provisions of this chapter apply to all land uses, development activity, and all structures and facilities within the City of Anacortes that are within the critical area, within the maximum buffer distance of, or likely to affect the functions and values of, one or more critical areas.

~~B.~~ Relationship to other regulations.

1. Shorelines of the state and shorelands as defined in RCW 90.58.030, and critical areas occurring within the jurisdiction of shorelines of the state and shorelands ("shoreline jurisdiction"), are regulated and protected by through the Anacortes Shoreline Master Program, (AMC Title 18.1619.72), Shoreline Master Program, including Appendix A– Shoreline Critical Areas Regulations, as amended. Activities occurring within shoreline jurisdiction are reviewed through the shoreline permit review and issuance process; a separate critical areas permit is not required. The Shoreline Master Program incorporates by reference portions of this Chapter (Ch. 19.70); however, certain provisions of this chapter that are not consistent with the Shoreline Management Act, 90.85 RCW and supporting Washington Administrative Code chapters, do not apply in shoreline jurisdiction.
2. These critical areas regulations apply in addition to zoning and other regulations adopted by the City. Notwithstanding AMC 19.12.040(E), in the event of any conflict between these regulations and any other regulations of the City, the regulations apply that provide greater protection to the critical areas' functions and values, as determined by the Decision Maker/Director.
3. When any provision of this chapter or any existing easement, covenant, or deed restriction conflicts with this chapter, that which provides more protection to the critical areas applies.
4. Compliance with the provisions of this Chapter does not constitute compliance with other federal, state, or local regulations and permit requirements that may be required. The applicant is responsible for complying with other agency requirements, apart from the process established in this Chapter.

Commented [TC1]: Change to:

~~A.~~ Unless explicitly exempted, the provisions of this chapter apply to all land uses, development activity, and all structures and facilities within the City of Anacortes that are within the critical area, within the maximum buffer distance of, or likely to affect the functions and values of, one or more critical areas.

Formatted: Indent: Left: 0.25", No bullets or numbering

#### 19.70.020 Identification, classification, and rating of critical areas.

- A. Critical Areas Maps.** The general locations of many critical areas in Anacortes are displayed on the City of Anacortes' Critical Areas Maps, which are hereby adopted by reference. The maps are used to alert the public of the potential location of critical areas in Anacortes. As new environmental information related to critical areas becomes available, the City is authorized to make changes as necessary to the Critical Areas Maps.
- B. Actual site conditions.** Regardless of whether a critical area is shown on the Critical Areas Map, the actual presence or absence of the features defined in this code as critical areas will govern. The City Prior to acting on any development permit the City may require an applicant to submit technical information to indicate whether critical areas actually exist on or adjacent to the applicant's site based on the definitions of critical areas in this code. This will be administered as a critical area identification form AMC 19.70.110 included with appropriate permit forms.
- C. Classification and rating.** To promote consistent application of the standards and requirements of this chapter, critical areas within the City will be rated or classified using best available science according to their characteristics, function and value, and/or their sensitivity to disturbance.
1. Classification of critical areas will be determined by the City using the following tools:
    - a. Application of the criteria contained in these regulations;
    - b. Consideration of the critical area reports submitted by qualified professionals in connection with applications subject to these regulations; and
    - c. Review of maps and other resources adopted pursuant to this chapter.
  2. Rating categories will not change due to illegal modifications. If the development proposal site contains or is within a critical area suspected of illegal modifications the rating will be based on pre-modification conditions of the critical area. Abatement of the unauthorized modification will be required prior to authorization of the current development proposal being processed for the subject site.

Formatted: Indent: Left: 0.06", Hanging: 0.44", No bullets or numbering

#### 19.70.025 Protection of critical areas.

- A.** Critical areas and their required buffers may not be altered except as allowed by this Chapter.
- B.** Any action taken pursuant to this chapter must result in equivalent or greater functions and values of the critical areas associated with the proposed action, as determined by the best available science.
- C.** All actions and development must be designed and constructed in accordance with mitigation sequencing per AMC 19.70.135-125 to achieve no net loss of critical area functions and values.
- D.** Applicants must first demonstrate an actual inability to avoid or reduce impacts, before restoration and compensation of impacts will be allowed.

- E. No activity or use may be allowed that results in a net loss of the functions or value of critical areas.
- F. Any individual critical area adjoined by another type of critical area must have the buffer and meet the requirements that provide the most protection to the critical areas involved.

#### 19.70.030 ~~General Requirements~~ Project Evaluation

- A. As part of the review, the city will:
  1. Verify the information submitted by the applicant;
  2. Evaluate the project area and vicinity for critical areas;
  3. Determine whether the proposed project is likely to impact the functions or values of critical areas; and
  4. Determine if the proposed project adequately addresses the impacts and avoids impacts to the critical area associated with the project.
- B. If the proposed project is within, adjacent to, or is likely to impact a critical area, the city will:
  1. Require a critical area report from the applicant that has been prepared by a qualified professional, to be reviewed and evaluated;
  2. Determine whether the development proposal conforms to the purposes and performance standards of this chapter, including the criteria in AMC 19.70.030035, Review criteria;
  3. Assess the potential impacts to the critical area and determine if they can be avoided or minimized; and
  4. Determine if any mitigation proposed by the applicant is sufficient to protect the functions and values of the critical area and public health, safety, and welfare concerns consistent with the goals, purposes, objectives, and requirements of this chapter.

#### 19.70.035 Critical Areas Review.

- A. **When required.** A proposal to modify any critical area and/or required buffer including, but not limited to, clearing, grading, draining, removal or alteration of vegetation, construction of structures, utilities and related infrastructure must require a critical area permit unless it qualifies as an exemption, as provided in AMC 19.70.0350040. Except for within shoreline jurisdiction, administration of this chapter shall be through the SMP and appropriate Shoreline Permit administration process.
- B. **Best Management Practices.** All activities, including those allowed without critical areas review, must be conducted using the best management practices appropriate for that activity that result in the least amount of impact to the critical areas. Best management practices must be used for tree and vegetation protection, construction management, erosion and sedimentation control, water quality protection, and regulation of chemical applications. The use of best management

practices is required to ensure that the activity does not result in degradation to the critical area. Appropriate BMP sources include Ecology's Construction Storm Water General Permit and NRCS Conservation Practices. Any incidental damage to, or alteration of, a critical area and/or buffer must be restored, rehabilitated, or replaced at the responsible party's expense.

**C. Modifications to Existing Nonconforming Structures and Uses.** In these provisions the burden of proof is on the applicant to bring evidence in support of their position. Existing structures, activities, and uses that were established legally but do not meet the current critical area, buffer, or buffer setback requirements may continue in accordance to AMC 19.49.040, and may be modified as follows:

1. Routine maintenance and repairs;
2. Structural modifications or additions that do not intensify the nonconformity of the structure or increase the area of hardscape lying within the critical area or buffer. The ~~Decision maker~~Director may require an updated critical areas report to confirm location of buffers and that the addition is located entirely outside the critical area or buffer;
3. Vertical additions above the ground floor that do not encroach further into the critical area or buffer beyond the existing exterior walls, except that critical areas review is required for additions in landslide hazard areas or buffers;
4. Restoration or replacement of a structure that is damaged by fire, natural disaster or other calamity when:
  - a. A complete application for reconstruction or replacement is submitted within one year of the damage; and
  - b. The restoration or replacement is made to conform to the current critical areas regulations, or if such regulations cannot be physically met without reducing the size of the building, the restoration or replacement may not intensify any nonconformity that existed prior to the damage.

c. Except that critical areas review is required for restoration and replacement in landslide hazard areas or buffers.

5. State Ferry Terminal. The existing developed footprint, except for infill between the toll booth area in the lowest parking lot, hillside walking paths, and a hillside side slope along the western side of the main terminal parking lot, and including all associated parking, at the Washington State Ferry Terminal facility. Redevelopment may occur within the existing footprint only, provided there is no net loss of ecological function and value in the adjacent buffer areas for Cannery Pond and Ship Harbor Interpretive Preserve wetlands.

**D. Demolition.** Demolition of structures located within critical areas or their buffers is permitted, excluding demolition of structures necessary to support or stabilize landslide hazard areas and will be subject to approval of a stormwater pollution prevention plan consistent with the

Commented [TC2]: Add section 5:

5. State Ferry Terminal. The existing developed footprint, except for infill between the toll booth area in the lowest parking lot, hillside walking paths, and a hillside side slope along the western side of the main terminal parking lot, and including all associated parking, at the Washington State Ferry Terminal facility, shall not be increased and redevelopment may occur provided there is no net loss of ecological function and value in the adjacent buffer areas for Cannery Pond and Ship Harbor Interpretive Preserve wetlands.

adopted stormwater management manual and clearing limits that will adequately protect the critical area.

#### 19.70.040 Exempt Activities.

- A. General requirements for all exempt activities.** Activities listed in this section are exempt from the rest of the provisions of this chapter only if they meet the specific terms of this section.
- B.** To be exempt from this chapter does not give permission to degrade a critical area or buffer or to ignore risk from natural hazards. All exempt activities must use reasonable methods to avoid potential impacts to critical areas and buffers. In every case, disturbance to the critical area must be minimized through best management practices and the use of low-impact equipment.
- C.** Any incidental damage to, or alteration of, a critical area or buffer that is not a necessary outcome of the exempted activity must be restored, rehabilitated, or replaced at the responsible party's expense.
- D.** This chapter may not exempt ~~this an~~ activity from the provisions of other [City permits such as Clearing and Grading for vegetation removal or ground disturbing activity or](#) agency permit requirements such as Washington Department of Fish and Wildlife [Hydrologic/Hydraulic](#) Permit, or Army Corp of Engineers regulatory requirements.
- E. Burden of proof.** [The burden of proof is on the applicant to bring forth evidence that the activity meets the precise description of Exemption.](#)

~~D.~~

#### ~~E.~~ Table 19.70.040 Exempt Activities

Table 19.70.040 (A) describes activities that must meet the precise description to be allowed without following a critical area process. Activities are divided into the categories of permitted in the Critical Area and permitted in the Buffer, marked by a yes or no in the appropriate column.

| EXEMPT ACTIVITIES:- (No review required, must strictly meet standards)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Critical Area | Buffer |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| <b>Emergencies.</b> Alterations in response to emergencies which threaten the public health, safety, and welfare or which pose an imminent risk of damage to private property, and that require remedial or preventative action in a timeframe too short to allow for compliance with the requirements of this chapter, if the following requirements are met: <ul style="list-style-type: none"> <li>a. Only the minimum intervention necessary to reduce the risk to public health, safety, or welfare and/or the imminent risk of damage to private property may be authorized by this exemption.</li> <li>b. The alteration undertaken must be reported to the <a href="#">Decision maker/Director</a> no later than 30 days after the alteration has occurred. Once notified, the <a href="#">Decision maker/Director</a> must</li> </ul> | Yes           | Yes    |

**Commented [CT3]:** Remember to add a clause that even if an activity does not require a CA permit if the activity is in the vicinity of CA's and meets the definition of clearing or grading – then the activity will be administered through a clearing/grading permit. → with an edit to those code sections to disqualify the thresholds if in the vicinity of CA or Buffer

| EXEMPT ACTIVITIES:- (No review required, must strictly meet standards)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Critical Area | Buffer |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|
| <p>confirm that an emergency existed and determine what, if any, additional applications and/or measures are required of the property owner to protect the critical area(s) consistent with the provisions of this chapter, and to repair any damage to a pre-existing resource.</p> <p><del>e. If the Decision maker determines that the action taken, or any part of the action taken, was beyond the scope of an allowed emergency action, the Decision maker</del><u>Decision-maker may take action to enforce this chapter consistent with AMC Title 19 and AMC Title 20.</u></p> <p>c. <del>A:</del> After the emergency, the person or agency undertaking the action must fully fund and conduct necessary site evaluations and critical area reports, mitigation plans, and restoration for any impacts to the critical area and buffers resulting from the emergency action. The person or agency undertaking the action must meet the review procedures contained herein. Mitigation activities must be initiated within one year of the date of the emergency or as directed by the Department.</p> <p>d. <u>If the Director determines that the action taken, or any part of the action taken, was beyond the scope of an allowed emergency action, or any required mitigation, the Director may take action to enforce this chapter consistent with AMC Title 19 and AMC Title 20.</u></p> |               |        |

#### 19.70.045 Permitted Alterations.

**A. Applicability.** An applicant may seek an alteration of a critical area and/or critical area buffer through a permitted alteration when application of the standards renders compliance with these provisions as infeasible and the proposed development meets the specific terms of this section and can be considered a reasonable use.

**B. General requirements.** The actions in the permitted alteration table below, must be considered permitted alterations, unless as otherwise specified under AMC 19.70.240 Specific Wetland Category Development Standards, and provided they are consistent with the general standards for mitigation sequencing and other applicable requirements established in this chapter.

Formatted: Indent: Left: 0.5", No bullets or numbering

~~B.~~

#### C. Review Process:

1. A critical area permit must be required for all permitted alterations. Requests for such permits must be reviewed using the procedures outlined in chapter 19.20, table 19.20.030. No permit must be issued unless it can be shown that the proposed development is fully consistent with the requirements of this chapter.
2. In addition to other project related documents, all permitted alterations must require a critical area assessment report per section 19.70.115 to evaluate the permitted alteration. The report must include:
  - a. A description of the function and condition of the critical area and or buffer that would be altered;
  - b. An analysis of the effect of the development proposal on the critical area and or buffer;

- c. A description of actions that can be taken to modify the development proposal to avoid or reduce the alteration of the critical area and/or buffer and a discussion of whether these modifications are practical and reasonable;
  - d. A mitigation plan as required by this chapter.
3. Burden of proof. The burden of proof is on the applicant to bring forth evidence in support of the application and upon which any decision has to be made on the application.
4. Public comment. Consistent with AMC 19.20.030The City must ensure the opportunity for public comment, including that from appropriate Federal, State, and Tribal natural resource agencies, to ensure the use of best available science before deciding on approval.
- D. Decision criteria.** A permit for alterations to of a critical areas and/or buffer width requirements of this Chapter may only be issued if the applicant demonstrates that all of the following criteria are met:
- 1. Special circumstances applicable to the subject property, including size, shape, or topography, and the strict application of this chapter is found to deprive the subject property of rights and privileges enjoyed by other properties in the vicinity; provided, however, that the fact that those surrounding properties have been developed under regulations in force prior to the adoption of this chapter may not be the sole basis for granting approval;
  - 2. The issuance of a variance to zoning requirements (setback, height, coverage, etc.) by itself will not provide sufficient relief to avoid the need for a permitted alteration to the critical area and/or buffer and other requirements for the critical areas regulated by this Chapter;
  - 3. Mitigation sequencing per AMC 19.70.~~135~~125(A) has been applied;
  - 4. The proposed alteration is supported by best available science; and
  - 5. The proposed alteration allows for development of the subject parcel with the least impact on critical areas while providing a reasonable use of the property.
- E. Conditions may be required.** In granting any approval, conditions and safeguards may be prescribed as are necessary to secure adequate protection of critical areas from adverse impacts, protect adjacent property, and to ensure conformity with this chapter.
- F. Table 19.70.~~040~~045**Permitted Activities.

Table 19.70.045 describes activities that must meet the precise description to be allowed ~~with~~ following the prescribed critical area process. Activities are divided into the categories of permitted in the Critical Area and permitted in the Buffer, marked by a yes or no in the appropriate column.

| Permitted Alterations: <del>(Critical Area Permit Required – Type 2 Administrative Decision)</del>                                                   | Critical Area | Buffer |

| <del>New to Table</del> <a href="#">Anacortes Community Forest Lands. Given the unique qualities of the community forest, all properties designated as ACFL have been nominated as a regulated critical area. Any and all new uses and development of new facilities within the ACFL must meet the requirements of the Conservation Easements/Deed Restrictions of the land, Anacortes</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Yes           | Yes    |

Commented [TC6]: Change to:

*Recreational Areas / Facilities.* Low impact activities which are consistent with the purpose and function of the critical area buffer and do not detract from its integrity may be permitted within the buffer (not including the ACFL), depending on the sensitivity of the critical area.

A. Limited public park or public recreational access including but not limited to trails, viewing platforms, fishing access (no wider than 6 foot), and foot bridges, provided that all of the following are satisfied:

- a. The area/facility is part of a public park that is dependent on its location for recreational function; and
- b. The area/facility is limited to the minimum necessary to accomplish the recreational function; and
- c. The removal of trees and native vegetation is minimized; and
- d. The balance of the development is consistent with other requirements of this chapter; and
- e. The project is identified in the Anacortes Comprehensive Plan or Parks Comprehensive Plan .

B. Private pedestrian walkways and public trails must meet the following standards:

- a. The trail is generally parallel to the perimeter of the critical area;
  - b. The trail is located in the outer 25% of the buffer area and is designated to avoid removal of trees and native vegetation;
  - c. The trail does not exceed 6 feet in width, and is limited to native soils or pervious surfaces. Raised boardwalks utilizing non-treated pilings may be acceptable; and
- The trail may be subject to closure during critical spawning, migration or breeding time periods of sensitive species that are present.

C. Informational signs. Construction and placement of informational signs or educational demonstration facilities no more than 9 square feet surface area and 4 feet high, as long as there is no permanent infringement on hydrology or stream flow and non-treated wood is used;

D. Limited excavating and filling necessary for the repair and maintenance of piers, walkways, observation decks, wildlife management shelters, boathouses, and other similar water related structures, provided they are built on pilings to allow unobstructed flow of water and preserve the natural contour of the wetland, except as authorized by special permit.

Commented [CT8]: Add:

Regulated Activities in Critical Aquifer Recharge Areas. All regulated activities listed under AMC 19.70.540.

Formatted: Font: Not Bold

#### 19.70.050 Reasonable ~~use~~ [Use exception](#) ~~Exception and~~ [Critical Area Variance](#).

- A. **Applicability.** If the application of this Chapter would result in denial of all reasonable and economically viable use of a property, and if such reasonable and economically viable use of the property cannot be obtained by consideration of a permitted alteration pursuant to AMC 19.70.040~~045~~, then a landowner may seek a reasonable use exception from the standards of this Chapter. Reasonable use exceptions are considered a critical area variance and are intended as a last resort and only when a variance can meet the requirements of this Chapter.
- B. **General Requirements.** Reasonable use is a legal concept articulated by federal and state courts in regulatory takings cases. Within the context of these cases and for the purposes of this title, reasonable use means uses allowed by the underlying zoning designation and subdivision of property is not allowed. When no possible alternative exists, a reasonable use exceptions must be considered a critical area variance, provided they are consistent with the general standards for variances under 19.38.040 and other applicable requirements established in this chapter.
- C. **[Procedures for Review](#) ~~process~~:**
1. A variance permit must be required for all reasonable use exceptions. Requests for such permits must be reviewed using the procedures applicable to Type 3 Hearing Examiner decisions outlined in chapter AMC 19.20.030. ~~A~~[No](#) permit ~~may not~~ must be issued unless it can be shown that the proposed development is fully consistent with the variance approval criteria enumerated in AMC Section 19.38.040 (variance criteria) as well as all of the requirements of this chapter.
  2. In addition to other project related documents, all ~~permitted alterations~~[critical area variances](#) must require a critical area assessment report per section AMC 19.70.125~~115~~ to evaluate the ~~permitted alteration~~[proposed disturbance](#). The report must include:
    - a. A description of the function and condition of the critical area and or buffer that would be altered;
    - b. An analysis of the effect of the development proposal on the critical area and or buffer;
    - c. A description of actions that can be taken to modify the development proposal to avoid or reduce the alteration of the critical area and/or buffer and a discussion of whether these modifications are practical and reasonable;

- d. A mitigation plan as required by this chapter.
  - 3. Burden of proof. The burden of proof is on the applicant to bring forth evidence in support of the application and upon which any decision has to be made on the application.
  - 4. [Public Comment. Consistent with AMC 19.20.030](#) The City must ensure the opportunity for public comment, including that from appropriate Federal, State, and Tribal natural resource agencies, to ensure the use of best available science before ~~deciding on approval~~ [a decision is made](#).
- D. **Variance criteria.** A reasonable use exception may be granted only if the applicant demonstrates that all of the requested action is consistent with all of the variance approval criteria as set forth:

- ~~a-1.~~ The application of this chapter would deny all reasonable economic use of the property and that there is no reasonable economically viable use with a lesser impact on the critical area than that proposed; and
- 2. Special conditions and circumstances exist that are peculiar to the land, the lot, or something inherent in the land, and that are not applicable to other lands subject to the provisions of this chapter; and
- 3. The inability of the applicant to derive reasonable use of the property is not the result of actions by the current or previous owner in subdividing the property or adjusting a boundary line, thereby creating the undevelopable condition, after the effective date of the ordinance codified in this Chapter; and
- 4. Any proposed modification to a critical area will be evaluated through consideration of a critical areas report and mitigation plan prepared by a qualified professional pursuant to the requirements of this Chapter, and will be the minimum necessary to allow reasonable and economically viable use of the property. The critical areas report and mitigation plan must be prepared utilizing best available science; and
- 5. Mitigation sequencing per AMC 19.70.~~135~~[125](#)(A) has been applied, and the proposal mitigates impacts on the critical area to the maximum extent possible, while still allowing reasonable use of the lot; and
- 6. The proposed development does not pose a threat to [adjacent property or to](#) the public health and safety; and
- 7. The applicant has demonstrated that the criteria in AMC 19.38.040 (variance criteria) are met; and
- 8. Granting the variance requested will not confer on the applicant any special privilege that is denied by this chapter to other lands, structures, or buildings under similar circumstances; and
- 9. The granting of the variance is consistent with the general purpose and intent of the Anacortes Comprehensive Plan, and planning policies.

Formatted

- E. **Conditions.** Conditions of approval may be included as part of the decision, including modifications to the size and placement of structures and facilities to minimize impacts to critical areas and associated buffers and mitigation requirements that ensure that all impacts are mitigated to the maximum extent feasible utilizing best available science.
- F. **Variances – Geologically hazardous areas.** A variance must not authorize development within a geologically hazardous area or required setback or buffer from a geologically hazardous area unless a Qualified Professional has determined the development will not pose a threat to public safety or property.

---

## **PART 1: CRITICAL AREAS REVIEW PROCEDURES**

---

### **19.70.110 Critical area identification form.**

Prior to the City's consideration of any proposed activity ~~allowed pursuant to Permitted Activities AMC 19.70.040 or~~ found not to be exempt under AMC 19.70.035040, the applicant must submit to the Department a completed form identifying suspected critical areas on, and within 300 feet, of the site.

### **19.70.115 Critical Area Report.**

- A. **Report required.** When the ~~Decision-maker determines~~ Director determines a proposed development is within, abutting, or is likely to adversely affect a critical area or buffer pursuant to the provisions of this chapter, ~~he/she must have the authority to~~ to the Director may require a critical areas assessment report that is, prepared by a Qualified Professional. The assessment of critical areas and analysis of impacts must be commensurate with the value or sensitivity of a particular critical area and relative to the scale and potential impacts of the proposed activity. This provision is not intended to expand or limit an applicant's other obligations under WAC 197-11-100.
- B. **Third Party Review of Critical Area Reports.** The ~~Decision-maker~~ Director may require, at the applicant's expense, a third-party review of a critical area report by a Qualified Professional under contract with or employed by the City in any of the following circumstances:
1. The project requires a critical area permit, or critical area variance; or
  2. Third party review is specifically required by the provisions of this chapter for the critical area(s) or critical area buffer(s) potentially being impacted; or
  3. When the ~~Decision-maker~~ Director determines that such services are necessary to demonstrate compliance with the standards and guidelines of this chapter or other appropriate regulations.
- C. **Critical Area Report Types or Sections.** Critical area report requirements may be met in stages through multiple reports or combined in one report. A critical area report must include one or more of the following sections or report types unless exempted by the ~~Decision-maker~~ Director based on the extent of the potential critical area impacts. The scope and location of the

proposed project will determine which report(s) alone or combined are sufficient to meet the critical area report requirements for potentially impacted critical area type(s). The typical sequence of required sections or reports that will fulfill the requirements of this section include:

1. **Reconnaissance.** The existence, general location, and type of critical areas on, adjacent to, or likely to be impacted by activities on a project site. Determination of whether the project will adversely impact or be at risk from the potential critical areas based on maximum potential buffers for the particular critical area type. Possible application of exemptions should also be addressed;
2. **Delineation.** The extent, boundaries, rating or classification, and applicable standard buffers of critical areas where the project area could potentially impact the critical area or its buffer including an assessment of the characteristics of or functions and values of the critical area and buffers identified;
3. **Analysis.** The proposal and impact assessment report documenting the potential project impacts to the critical area and buffers including a discussion of the efforts taken to avoid, minimize, and reduce potential impacts to those areas per AMC 19.70.125(A);
4. **Mitigation.** The measures that prevent or compensate for the potential impacts of the project designed to meet the requirements of this chapter, AMC 19.70.125, Mitigation Plan Requirements, and the standards for the specific critical areas impacted. Mitigation includes, but is not limited to, adjustments to required buffer sizes, best practices to minimize impacts, and critical area or buffer enhancement, restoration, or preservation plans. Mitigation plans include but are not limited to habitat management plans, revegetation or replanting plans, and restoration plans;
5. **Maintenance and Monitoring.** The goals of the mitigation proposed, performance standards for success, monitoring methods and reporting schedule, and contingency actions. Maintenance and monitoring plans must be consistent with the mitigation performance standards and requirements of this chapter, including the specific mitigation plan requirements outlined in each critical area type section.

**D. Minimum Report Requirements.** At a minimum, critical area reports must contain the following information:

1. The names and qualifications of the persons preparing the report and documentation of any fieldwork performed on the site;
2. A description of the proposal, proposal location including address and parcel number(s), and a vicinity map for the project;
3. Identification and characterization of all critical areas, water bodies, shorelines, and buffers on or within 300 feet of the proposed project area, The [Decision-maker](#) [Director](#) may require critical area and buffer dimensions be accurately surveyed, depending on the scope of the project;

4. Documentation of any fieldwork performed on the site, including field data sheets, for delineations, rating system forms, baseline hydrologic data, site photos, etc.;
5. A statement specifying the accuracy of the report and all assumptions made and relied upon;
6. A description of methodologies used to conduct the critical areas investigation, including references;
7. A scaled drawing of critical areas and buffer identified in the report including buffers for off-site critical areas that extend onto the project site.

**E. Existing reports.** Critical areas assessment reports must generally be valid for a period of five years. Unless otherwise provided, a critical areas report may incorporate, be supplemented by, or composed of any reports or studies required by other laws and regulations or previously prepared for and applicable to the development proposal site, as approved by the [Decision maker/Director](#). At the discretion of the [Decision maker/Director](#), reports previously compiled or submitted as part of a proposal for a development may be used as a critical areas report to the extent that the requirements of this section and the requirements for each specific critical area type are met. Supplemental critical area report(s) may be required to provide information or analysis to address changes to the project scope, potential impacts or to changes to applicable regulations that have been made subsequent to existing, valid critical area reports, or other circumstances.

**F. Modifications to Report Requirements.** The applicant may consult with the [Decision maker/Director](#) prior to or during preparation of the critical areas report, to obtain approval of modifications to the required contents of the report where, in the judgement of a qualified professional, more or less information is required to adequately address the potential critical area impacts and required mitigation.

**4.1.1** In some cases, such as when it is determined that no specific critical area is present, a full report may not be necessary to determine compliance with the critical area regulations, and in those cases a letter or reconnaissance only report may be required.

**5.2.2** Limitations to study area. The [Decision maker/Director](#) may limit the required geographic area of the critical areas report as appropriate if:

- a. The applicant, with assistance from the City of Anacortes, cannot obtain permission to access properties adjacent to the project area; or
- b. The proposed activity will affect only a limited part of the project site.

#### 19.70.120 Application Requirements.

**A. A.** A complete application for a [critical area Permitted Alteration](#) permit or [critical area Reasonable Use Exception](#) permit must include the following information and

**Formatted:** Indent: Left: 0.5", Outline numbered + Level: 3 + Numbering Style: 1, 2, 3, ... + Aligned at: 0.38" + Indent at: 0.63", Tab stops: 1.06", Left

**Formatted:** Indent: Left: 0.81", Outline numbered + Level: 5 + Numbering Style: a, b, c, ... + Aligned at: 0.75" + Tab after: 1.25" + Indent at: 1", Tab stops: Not at 1.25"

**Formatted:** Heading 3, Indent: Left: 0"

materials on a form provided by the ~~Decision-maker~~[Director](#). For the purpose of this section, a complete application includes:

1. The name and contact information of the applicant;
2. Adequate information to determine compliance with the requirements of the critical area regulations, including a critical area report, impact and hazard assessment, and mitigation requirements specific to each critical area type, as indicated in the corresponding sections of this chapter;
3. Identification of the development permit(s) requested and all other local, State, and/or Federal critical area-related permits required for the project;
4. Site plan, a scaled drawing of the development proposal including:
  - a. Property and project site boundaries.
  - b. An accurate depiction of all critical areas, including off-site critical areas and buffers that extend onto the project site, a desk survey is acceptable when access to the adjacent property has been denied.
  - c. The development proposal, including grading and clearing limits and areas of proposed impacts to critical areas and/or buffers (include square footage estimates).
  - d. A scaled depiction and description of the proposed stormwater pollution prevention plan consistent with the adopted stormwater manual, for the development and consideration of impacts to critical areas due to drainage alterations;
  - e. ~~5-~~ An assessment of probable impacts to the critical areas resulting from the proposed development of the site based upon identified findings;
  - f. ~~6-~~ A description of reasonable efforts made to apply mitigation sequencing pursuant to AMC 19.70.135, Mitigation requirements, to avoid, minimize, and mitigate impacts to critical areas; and
  - g. ~~7-~~ Plans for mitigation required to offset any critical areas impacts, in accordance with AMC 19.70.140, Mitigation plan requirements, and the corresponding mitigation performance standards sections of this chapter, including a discussion of the applicable development standards and cost estimates for determination financial guarantee requirements.

- B. **Additional Requirements.** The ~~Decision-maker~~[Director](#) may require additional information to be included in the critical areas permit submittal when determined to be necessary to the review of the proposed activity in accordance with this chapter. Additional information that may be required includes, but is not limited to:

Formatted: Indent: Left: 0.81", Hanging: 0.25"

1. Historical data, including original and subsequent mapping, historical aerial photographs, data compilations and summaries, and available reports and records relating to the site or past operations at the site;
2. Grading and stormwater management plans; and
3. Information specific to the type, location, and nature of the critical area.

#### **19.70.125 Mitigation requirements.**

Mitigation must be sufficient to restore impacted functions and values, or compensate for the impacted functions and values of the critical area and to prevent risk from a hazard posed to a critical area by the proposed activity. Mitigation must not be implemented until after the ~~Decision-maker~~[Decision-maker](#) has provided approval of a critical areas report that includes a mitigation plan.

- A. **Mitigation sequencing.** This section applies to mitigation required with all critical areas reviews, approvals, and enforcement pursuant to this chapter. This section is supplemented with specific measures under [parts subchapters](#) for particular critical area types. Mitigation for specific development proposals may include a combination of the measures below and must be designed and constructed in accordance with the provisions of this section. Before impacting any critical areas, an applicant must demonstrate that the following actions have been taken in the following sequential order:
  1. Avoiding the impact altogether by not taking a certain action or parts of actions;
  2. Minimizing impacts by limiting the degree or magnitude of the action and its implementation by using appropriate technology, or by taking affirmative steps, such as project redesign, relocation, or timing, to avoid or reduce impacts;
  3. Rectifying the impact by repairing, rehabilitating, or restoring the affected environment or by restoring or stabilizing the critical area through natural, engineering, or other methods;
  4. Reducing or eliminating the impacts or hazard over time by preservation and maintenance operations during the life of the action;
  5. Compensating for the impact by replacing, enhancing, or providing substitute resources or environments; and/or
  6. Monitoring, measuring and reporting the impact to the ~~Decision-maker~~[Decision-maker](#) and taking appropriate corrective measures.
- B. ~~Applicants must first demonstrate an inability to avoid or reduce impacts before the use of actions to mitigate potential impacts will be allowed. No activity or use may be allowed that results in a net loss of the functions or values of a critical area.~~
- C. **Type, Location and Timing of Mitigation.** Unless it is demonstrated that higher level of ecological functioning or greater reduction of hazard risk would result from an alternative approach or as otherwise allowed in this chapter, mitigation for adverse impacts must be based on best available science and must be in-kind, on-site, and prior to the activities that will

disturb the critical area. Mitigation measures that cannot be implemented prior to the critical area impacts must be completed immediately following disturbance and prior to use or occupancy of the action or development. Construction of mitigation projects must be timed to reduce impacts to existing fisheries, wildlife, and flora.

1. The ~~Decision-maker~~[Decision-maker](#) may authorize a one-time temporary delay in completing construction or installation of the mitigation when the applicant provides a written explanation from a ~~Qualified~~[Professional-Professional](#) as to the rationale for the delay and satisfactory financial guarantee that the installation will occur. An appropriate rationale would include identification of the environmental conditions that could produce a high probability of failure or significant construction difficulties (e.g. project delay lapses past a fisheries window, or installing plants should be delayed until the dormant season to ensure greater survival of installed materials). The delay must not create or perpetuate hazardous conditions or environmental damage or degradation, and the delay must not be injurious to the health, safety, or general welfare of the public.
2. **Alternative mitigation approaches.** If the applicant can demonstrate that off-site concurrent or advance mitigation would provide a higher level of ecological functioning or a greater reduction of hazard risk, off-site mitigation that occurs on Fidalgo Island will be considered by the ~~Decision-maker~~[Decision-maker](#).

#### 19.70.130 Mitigation plan requirements

When mitigation is required, the applicant must submit for approval by the City a mitigation plan as part of the critical area report. The mitigation plan must include:

- A. Environmental Goals and Objectives.** The mitigation plan must identify environmental goals and objectives of the mitigation proposed and including:
  1. A description of the anticipated impacts to the critical areas, the mitigating actions proposed, and the purposes of the compensation measures, including the site selection criteria; identification of compensation goals; identification of resource functions; and dates for beginning and completion of site compensation construction activities. The goals and objectives must be related to the functions and values of the impacted critical area; and
  2. A review of the best available science supporting the proposed mitigation and a description of the report author's experience to date in restoring or creating the type of critical area proposed.
- B. Performance Standards.** The mitigation plan must include measurable specific criteria for evaluating whether or not the goals and objectives of the mitigation project have been successfully attained at the end of the required monitoring period and whether or not the requirements of this chapter have been met.
- C. Detailed Construction Plans.** In order to convey proposed construction techniques and anticipated final outcome, the mitigation plan must include written specifications, descriptions, and drawings of the mitigation propose, including:

1. The proposed construction sequence, timing, and duration;
2. Best management practices including erosion and sediment control features to be implemented;
3. Site plans showing grading and excavation details, slope gradient, and final grade elevations with minimum two-foot contour intervals;
4. Cross-sectional drawings;
5. A planting plan specifying plant species, quantities, locations, size, spacing, and density; and
6. Measures to protect and maintain plants until established.

**D. Monitoring Program and Contingency Plan.** A monitoring and contingency plan is required for all projects requiring mitigation.

1. The mitigation plan must include a monitoring program to be implemented by the applicant to determine the success of the mitigation project and any necessary corrective actions. This program must determine if the original goals and objectives of the mitigation plan are being met.
2. A contingency plan must be established for indemnity in the event that the mitigation project is inadequate or fails. Contingency plans include identification of potential courses of action, and any corrective measures to be taken if monitoring or evaluation indicates project performance standards are not being met. Corrective measures must be taken when the qualified professional indicates, in a monitoring report, that the contingency actions are needed to ensure project success by the end of the monitoring period. A performance and maintenance bond, or other acceptable financial guarantee, is required to ensure the applicant's compliance with the terms of the mitigation agreement consistent with AMC 19.70.160, financial guarantee requirements.
3. Monitoring programs prepared to comply with this section must include the following requirements:
  - a. Best available scientific procedures must be used to establish the success or failure of the project. A protocol outlining the schedule for site monitoring (for example, monitoring must occur in years zero (as-built), one, three, and five after site construction), and how the monitoring data will be evaluated to determine if the performance standards are being met.
  - b. For vegetation determinations, permanent sampling points must be established.
  - c. The monitoring program must include measurable specific criteria, or performance standards, for evaluating whether or not the goals and objectives of the mitigation plan have been successfully attained.
  - d. A monitoring report must be submitted as needed to document milestones, successes, problems, and contingency actions of the mitigation project. Monitoring reports on the

current status of the mitigation project must be submitted, consistent with Subsection (e) of this section, to the City on the schedule identified in the monitoring plan, but not less than every other year. The reports are to be prepared by a qualified professional and reviewed by the City, or a qualified professional retained by the City, and should include monitoring information on wildlife, vegetation, water quality, water flow, stormwater storage and conveyance, and existing or potential degradation, as applicable.

- e. Monitoring programs must be established for a period necessary to establish that performance standards have been met, but not for less than a minimum of five years without approval from the ~~Decision-maker~~[Decision-maker](#). A longer monitoring period may be required depending on the mitigation goals.
  - f. If necessary, failures in the mitigation project must be corrected.
  - g. Dead or undesirable vegetation must be replaced with appropriate plantings.
  - h. Damage caused by erosion, settling, or other geomorphological processes must be repaired.
  - i. ~~The~~ mitigation project must be redesigned (if necessary) and the new design must be implemented and monitored, as in subsection (D)(3)(d) of this section.
  - j. Correction procedures must be approved by the ~~Decision-maker~~[Decision-maker](#); the ~~decision-maker~~[Decision-maker](#) may request review by a qualified professional.
  - k. If the mitigation goals are not obtained within the initial monitoring period, the applicant remains responsible for restoration of the impacted values and functions or hazard risk reduction until the mitigation goals agreed to in the mitigation plan are achieved.
- E. **Monitoring Reports.** Monitoring reports must be submitted to the City consistent with the approved monitoring plan.
- 1. The as-built report, required prior to final inspection, must, at a minimum, include documentation of the following:
    - a. Departures from the original approved plans;
    - b. Construction supervision provided by the qualified professional;
    - c. Approved project goals and performance standards;
    - d. Baseline data for monitoring per the approved monitoring methods;
    - e. Photos from established photo points; and
    - f. A site plan showing final mitigation as constructed or installed, monitoring points, and photo points.
  - 2. Subsequent monitoring reports must, at a minimum, include:
    - a. Monitoring visit observations, documentation, and analysis of monitoring data collected;
    - b. Photos from established photo points;

- c. Determination whether performance standards are being met; and
  - d. Maintenance and/or contingency action recommendations to ensure success of the project at the end of the monitoring period.
3. The applicant is responsible for reimbursement of the cost of review of monitoring reports and site inspections during the monitoring period which are completed by the City or a qualified professional under contract with or employed by the City.
- F. **Cost Estimates.** The mitigation plan must include cost estimates that will be used by the City to calculate the amounts of financial guarantees, if necessary, to ensure that the mitigation plan is fully implemented. Financial guarantees ensuring fulfillment of the compensation project, monitoring program, and any contingency measures must be posted in accordance with AMC 19.70.160, financial guarantee requirements.
- G. **Approved Mitigation Projects – Signature.** On completion of construction, an as-built report for any approved mitigation project must be prepared and signed off by the applicant’s qualified professional and approved by the City. Signature of the qualified professional on the required as-built report and approval by the ~~Decision-maker~~[Director](#) indicates that the construction has been completed as planned.

**19.70.135 Title Notification.**

- A. **Generally.** A critical area notice on title is required, as a condition of permit issuance or project approval, when a permit or development application is submitted for development on any property containing a critical area or buffer. The purpose is to inform subsequent purchasers of real property of the existence of critical areas.
- 1. The title notice requirement can be met through recording of a title notice on forms prepared by the City, establishment of a critical area tract, or recording of a native growth protection area easement, consistent with AMC 19.70.145(B) through (D) below, as applicable.
  - 2. The following must be noted on all critical area title notice documents:
    - a. Identification of ownership and long term maintenance responsibility of critical areas, buffers, and permanent field markings (e.g. fencing, signage);
    - b. Restrictions on development, vegetation removal, and application of hazardous substances (pesticides, herbicides, fertilizers) within the critical areas and buffers;
    - c. The right of the City to enforce the terms of the restrictions.
- B. **Title Notice.** The title notice applicable to the property must be approved by the ~~Decision-maker~~[Decision-maker](#) and City Attorney for compliance with this provision and be filed by the property owner, at their expense, with the Skagit County Auditor’s Office. The title holder will have the right to challenge this notice and to have it extinguished if the critical area designation

no longer applies. However, the titleholder is responsible for completing a critical area report, subject to approval by the ~~Decision-maker~~[Decision-maker](#), before the notice on title can be extinguished. The title notice runs with the land.

**C. Critical Area Tract.** Subdivisions, short subdivisions, and binding site plans must establish a separate critical areas tract as a permanent protective measure for wetlands, fish and wildlife habitat conservation areas, and ~~landslide~~[geological](#) hazard areas and their buffers. The plat or binding site plan for the project must note the long-term ownership/maintenance responsibility as well as clearly depict the critical areas tract, including all of the subject critical area, any required buffer, and any additional lands included voluntarily as part of the project. Should the critical area tract include several types of critical areas, separate critical areas tracts must be identified.

**D. Native Growth Protection ~~Easements~~Area (NGPANGPE).** ~~NGPA-NGPE~~ easements are required on a property where no subdivision, short subdivision, or binding site plan is proposed or required. Unless otherwise required in this chapter, ~~NGPA-NGPE~~ easements must be recorded on title for all affected parcels prior to approval of a development application or building permit, when two or more dwelling units and/or nonresidential development are proposed on one parcel, to delineate and protect critical areas and their buffers. The easement to be recorded must clearly depict the critical area(s), required buffer(s) and the limits of the ~~NGPA-NGPE~~ easement.

#### 19.70.140 Field marking.

**A. Temporary field marking during construction.** The outer perimeter of the critical area buffer and the clearing limits identified by an approved permit or authorization must be marked in the field with temporary "clearing limits" fencing in such a way as to ensure that no unauthorized intrusion will occur. The marking is subject to inspection by the ~~Decision-maker~~[Director](#) prior to the commencement of permitted activities. This temporary marking and fencing must be maintained throughout construction and may not be removed until permanent fencing and/or signs, if required, are in place.

**B. Permanent field marking.** The ~~Decision-maker~~[Decision-maker](#) may require installation of permanent signs, markers, and fencing along the outer perimeter of a critical area or its buffer when it is determined necessary to protect the critical areas' functions and values. Permanent markings must be installed prior to final project approval or occupancy, as determined by the ~~Decision-maker~~[Decision-maker](#).

1. **Signs.** All critical areas tracts, easements, and dedications, should be clearly marked on the site using permanent markings, as follows:

a. Signs must be placed at least every 50 feet, with a minimum of one per lot, which include the following text, or similar, as approved by the ~~Decision-maker~~[Decision-maker](#):

*City of Anacortes Designated Critical Area. Activities, including clearing and grading, removal of vegetation, pruning, cutting of trees or shrubs, planting of nonnative species, and other alterations may be prohibited. Help protect and care for this area. Please contact the City of Anacortes with questions or concerns.*

b. Signs must be made of an enamel-coated metal face and attached to a metal post or another non-treated material of equal durability.

2. **Fencing.** Permanent fencing should be designed so as not to interfere with species migration or wildlife movement, unless exclusion fencing is more pertinent, and constructed in a manner that minimizes impacts to the critical areas and buffers. Proposed fencing type and materials will be determined on a case by case basis and must be approved by the ~~Decision-maker~~[Decision-maker](#) prior to installation.

C. **Maintenance and replacement.** It is the responsibility of the landowner, successors, or as otherwise assigned to maintain in perpetuity and replace, if necessary, all permanent fencing and field markings.

#### **19.70.145 Construction plan review, monitoring, and inspection.**

- A. The ~~Decision-maker~~[Director](#) may require project building and construction plans be reviewed by a qualified professional for confirmation of consistency with the critical areas report and recommendations prior to approval of construction plans.
- B. The ~~Decision-maker~~[Director](#) may require monitoring by a qualified professional during site alteration activities within, or adjacent to, critical areas or buffers, and/or a final inspection report by the qualified professional stating that construction has or has not implemented the design recommendations provided in the project critical areas report, and evaluation of any deviation from the recommendations.
- C. When the ~~Decision-maker~~[Director](#) determines that such services are necessary to demonstrate compliance with the standards and guidelines of this chapter, they will be at the applicant's expense.

#### **19.70.150 Financial Guarantee Requirements.**

When determined necessary by the ~~Decision-maker~~[Director](#), bonds, and other financial guarantees, and associated performance agreements or maintenance/defect/monitoring agreements are required for projects with required mitigation or restoration of impacts to critical areas or critical area buffers consistent with the following:

- A. A performance agreement and bond, or other acceptable financial guarantees, are required from the applicant when mitigation required pursuant to a development proposal is not completed prior to final permit approval, such as final plat approval or final building inspection. The amount of the performance bond(s) must equal 125 percent of the cost of the mitigation project.
- B. A performance agreement and bond, or other acceptable financial guarantees, are required from the applicant when restoration is required for remediation of a critical area violation. The amount of the performance bond(s) must equal 125 percent of the cost of the mitigation project.
- C. A maintenance/defect/monitoring agreement and bond, or other acceptable financial guarantees, are required to ensure the applicant's compliance with the conditions of the approved mitigation

plan pursuant to a development proposal or restoration plan for remediation of a violation. The amount of the maintenance bond(s) must equal 125 percent of the cost of the mitigation project in addition to the cost for monitoring for a minimum of five years. The monitoring portion of the financial guarantee may be reduced in proportion to work successfully completed over the period of the bond. The bonding period must coincide with the monitoring period.

#### **19.70.165 Unauthorized Critical Area Alterations.**

- A. When a critical area or its buffer has been altered in violation of this chapter, all ~~development~~ work must stop and the critical area and buffer must be restored. The ~~Decision maker~~Director may issue a stop work order to cease all ~~development~~work, and order restoration measures at the owner's or other responsible party's expense to remediate the impacts of the violation of the provisions of this chapter.

#### **B. Requirement for Restoration Plan.**

1. All ~~work~~development must remain stopped until a restoration plan is prepared by the responsible party and an approved after the fact permit is issued by the City. Such a plan must be prepared by a ~~qualified~~Qualified professionalProfessional using the best available science and must describe how the actions proposed meet the minimum requirements described in subsection C of this section.
2. The ~~Decision maker~~Director may, at the responsible party's expense, seek expert advice, including but not limited to third party review by a qualified professional under contract with or employed by the City, in determining if the plan meets the minimum performance standards for restoration. Submittal, review, and approval of required restoration plans for remediation of violations of this chapter must be completed through a site development permit application process.

#### **C. Minimum Performance Standards for Restoration.**

1. For alterations to critical aquifer recharge areas, wetlands, and fish and wildlife habitat conservation areas, the following minimum performance standards must be met for the restoration:
  - a. The pre-violation function and values of the affected critical areas and buffers must be restored, including but not limited to hydrologic, water quality and habitat functions;
  - b. The pre-violation soil types and configuration must be replicated;
  - c. The critical area and buffers must be replanted with a native vegetation community that reproduces the structure, species content and condition of the pre-violation vegetation community. Based on the historical or pre-violation vegetation community, native plant species must be replaced at minimum of a 5:1 ratio or installed at a density of 5 foot-on-center unless

approved by the ~~Decision-maker~~Decision-maker. The pre-violation functions and values should be replicated at the location of the alteration; and

- d. Information demonstrating compliance with the requirements in AMC 19.70.140125, Mitigation plan requirements, and the applicable mitigation sections for the affected type(s) of critical area(s) and their buffer(s) must be submitted to the ~~Decision-maker~~Decision-maker with a complete site development permit application.
- e. These standards may be modified by the ~~Decision-maker~~Decision-maker when it can be demonstrated that greater functional and habitat values can be obtained.

2. For alterations to special flood hazard and geologically hazardous areas, the following minimum performance standards must be met for the restoration of a critical area:

- a. The hazard must be reduced to a level equal to, or less than, the pre-violation hazard;
- b. Any risk of personal injury resulting from the alteration must be eliminated or minimized; and
- c. The hazard area and buffers must be replanted with native vegetation sufficient to minimize the hazard.
- d. These standards may be modified by the ~~Decision-maker~~Decision-maker if the violator can demonstrate that greater safety can be obtained.

**D. Site Investigation.** The ~~Decision-maker~~Director is authorized to take such actions as are necessary to enforce this chapter. The ~~Decision-maker~~Director (or ~~Decision-maker~~Director's authorized representative) must present proper credentials and obtain permission before entering onto private property.

**E. Penalties.** Any responsible party violating the provisions of this chapter may be subject to applicable penalties per AMC Title 20 Civil Enforcement and Penalties plus the following:

- 3. A square footage cost of \$3.00 per square foot of impacted critical area buffer; and a square footage cost of \$15.00 per square foot of impacted critical area; and
- 4. A per tree penalty in the amount of \$3,000 per non-significant tree and \$9,000 per Significant Tree, for trees removed, or otherwise damaged, within a critical area or buffer in violation of the provisions of this chapter.

**19.70.170 Final Decision and Appeals.**

- A. **Completion of the critical area review.** The city's determination regarding critical areas pursuant to this chapter is final concurrent with the final decision to approve, condition, or deny the underlying permit for the development proposal or other activity involved.
- B. **Appeals.** Any decision to approve, condition, or deny a development activity proposal or other activity based on the requirements of this chapter may be appealed according to, and as part of, the appeal procedure for the underlying permit or approval involved.

---

## **PART 2: WETLANDS**

---

### **19.70.210 Wetlands – Description and Purpose.**

It is the purpose of this Chapter to protect the functions and values of wetlands, which serve many important ecological and environmental functions and help to protect public health, safety, and welfare by providing flood storage and conveyance, and erosion control, while also providing fish and wildlife habitat, recreation, water quality protection, water storage, education, scientific research opportunities and other public benefits.

### **19.70.215 Wetlands - Designation and Rating.**

**A. Designation.** All areas meeting the definition of a wetland and the wetland identification criteria pursuant to this chapter, regardless of any formal identification, are hereby designated critical areas and are subject to the provisions of this chapter.

**B. Rating.** Wetlands must be rated by a qualified professional according to the Washington State Department of Ecology Wetland Rating System for Western Washington - 2014 Update (Ecology Publication #14-06-029, October 2014), or as revised. Wetland rating categories will be applied as the wetland exists on the date of adoption of the rating system by the City, as the wetland naturally changes in accordance with permitted activities.

1. **Category I.** Category I wetlands are those that represent unique or rare wetland types, are more sensitive to disturbance than most wetlands, are relatively undisturbed and contain ecological attributes that are impossible to replace within a human lifetime, or provide a high level of functions. The following types of wetlands are Category I:
  - a. Relatively undisturbed estuarine wetlands larger than one acre;
  - b. Wetlands of high conservation value identified by scientists of the Washington Natural Heritage Program/Department of Natural Resources (DNR);
  - c. Bogs;
  - d. Mature forested wetlands larger than one acre;
  - e. Wetlands in coastal lagoons; and
  - f. Wetlands that perform many functions well and have a total score of 23 points or more in the wetland rating.
2. **Category II.** Category II wetlands are those wetlands that are difficult, though not impossible, to replace, and provide high levels of some functions. The following types of wetlands are Category II:
  - a. Estuarine wetlands smaller than 1 acre or disturbed estuarine wetlands larger than 1 acre;

- b. Wetlands with a moderately high level of functions and a total score of 20 to 22 points in the wetland rating.
  - c. Wetlands in coastal lagoons that are relatively undisturbed and equal to or smaller than 1/10 ac (4350 square feet).
3. **Category III.** Category III wetlands are those with a moderate level of functions, generally have been disturbed in some ways, can often be adequately replaced with a well-planned mitigation project, and are often less diverse or more isolated from other natural resources in the landscape than Category II wetlands. The following types of wetlands are Category III:
- a. Wetlands with a moderate level of functions with a total score of 16 to 19 points in the wetland rating.
4. **Category IV.** Category IV wetlands have the lowest levels of functions and are often heavily disturbed, with a total score of 15 points or less in the wetland rating. The functions provided by Category IV wetlands are generally easier to replace, and in some cases can be improved. However, experience has shown that replacement of functions cannot be guaranteed in any specific case. These wetlands may provide some important functions that need protected.
- B. **Illegal Modifications.** When a violation occurs wetland rating categories do not change due to illegal modifications or alterations. A wetland's category must be based on the pre-violation condition of the wetland.

#### 19.70.220 Wetlands – Mapping and delineation.

- A. **Mapping.** The approximate location and extent of potential wetlands are shown in the wetland data layer maintained in the City of Anacortes geographic information system (GIS). In addition, the following maps and inventories, that depict areas of hydric soils and potential wetland areas, are hereby adopted by reference as amended:
- 1. Soils maps produced by the U.S. Department of Agriculture, National Resources Conservation Service; and
  - 2. The National Wetlands Inventory, produced by the U.S. Fish and Wildlife Service.
- B. **Reference Only.** The maps and resources cited above are to be used as a guide for the Department, project applicants, and/or property owners and may be continuously updated as new critical areas are identified. They are a reference and do not provide a final critical area designation.
- C. **Identification and Delineation.** Identification of wetlands and delineation of their boundaries pursuant to this chapter must be done in accordance with the adopted Federal wetland delineation manual and applicable regional supplements per WAC [173-22-035](#). The exact location of a wetland's boundary must be determined through the performance of a field investigation by a qualified professional. Evidence documenting the results of the

boundary survey, including evidence of a lack of wetland indicators if no wetlands are identified, must be submitted to the City.

#### 19.70.225 Wetlands – General Development Standards.

- A. All development activities and uses are prohibited in wetlands and wetland buffers, except as provided for in this chapter, and only when it is demonstrated that the activity will not result in a loss of the functions and values of the wetland through the application of mitigation sequencing in AMC 19.70.135.
- B. **Exemptions.** Exemptions to this chapter are listed in the provisions established in AMC 19.70.035 Exemption activities.
- C. **Subdivisions.** The subdivision and/or short subdivision of land in wetlands and associated buffers are subject to the following:
  - 1. Land that is located wholly within a wetland and/or its buffer may not be subdivided; and
  - 2. Land that is located partially within a wetland and/or its buffer may be subdivided; provided they each lot will meet all zoning standards in AMC 19.42 without encroaching into the wetland or buffer. the minimum lot size calculations as required in AMC 19.40.

#### 19.70.230 Wetlands – Specific Wetland Category Development Standards.

- A. **Category I Wetlands.** Development activities and uses that result in alteration of Category I wetlands and their associated buffers are prohibited, unless the denial will prevent all reasonable economic use of the property. The development may be permitted through a Critical Area Variance if it is determined to be the minimum impact possible and a Reasonable Use as prescribed in AMC 19.70.045.
- B. **Category II, III and IV Wetlands.** Development activities that result in alteration of Category II, III or IV wetlands may be permitted upon demonstration, through a critical areas report meeting the requirements of this Chapter, that:
  - 1. Mitigation sequencing has been applied per AMC 19.70.135125(A);
  - 2. The proposed alteration will not degrade the quantitative and qualitative functioning of the wetland, or that any degradation can be adequately mitigated to protect or compensate for the wetland functions that are lost;
  - 3. Small, Hydrologically Isolated Category III and IV Wetlands (less than 1,000 sq. ft.). The Decision-makerDecision-maker may allow small, hydrologically isolated Category III and IV wetlands to be exempt from the requirement to avoid impacts (AMC 19.70.135125(A)(1) Mitigation requirements) and allow alteration of such wetlands if all of the following conditions are met:

Commented [CT9]: Change to:

3. Small, Hydrologically Isolated Category IV Wetlands (less than 1,000 sq. ft.). The Decision-maker may allow small, hydrologically isolated Category IV wetlands to be exempt from the requirement to avoid impacts (AMC 19.70.135(A)(1) Mitigation requirements) and allow alteration of such wetlands if all of the following conditions are met:

- a. The remaining mitigation sequencing actions of AMC 19.70.135125(A) (2)-(6) are followed;
  - b. The wetland is less than 1,000 square feet in area;
  - c. The wetland does not have unique characteristics that would be difficult to replace through standard compensatory mitigation practices.
  - d. The wetland is a low quality Category III or IV wetland with a habitat score of less than 5 points in the adopted rating system;
  - e. The wetland does not provide significant suitable breeding habitat for native amphibian species. Suitable breeding habitat may be indicated by adequate stable and seasonal inundation that is persistent from February to at least through April and presence of thin-stemmed emergent vegetation and/or clean water;
  - f. The wetland does not contain habitat identified as essential for local populations of priority species identified by the Washington Department of Fish and Wildlife or species of local importance which are regulated as fish and wildlife habitat conservation areas in [Chapter 19.70.300 Part 3 \(FWHCA\\_section\)](#);
  - g. The wetland is not associated with shorelines of the state or their associated buffers;
  - h. The wetland is not associated with riparian areas or buffers;
  - i. The wetland is not part of a wetland mosaic; and
  - j. A mitigation plan to replace lost wetland functions and values is developed, approved, and implemented consistent with AMC 19.70.140125.
  - k. In order to verify that the wetland meets these exemption conditions, a critical area report for wetlands meeting the requirements in this chapter must be submitted.
4. Small, Hydrologically Isolated Category III and Category IV Wetlands (less than 1,000 sq. ft.). Wetlands less than 1,000 square feet that meet the criteria in subsection (B)(3) of this section (above) and that do not contain federally listed species or their critical habitat are exempt from the buffer provisions contained in this Chapter. In order to verify that the wetland meets this exemption, a critical area report for wetlands meeting the requirements in this chapter must be submitted.

#### 19.70.235 Wetlands – Required buffer areas.

- A. **Buffer Requirements.** Wetland buffers must be established to protect the integrity, functions and values of the wetland. The standard buffer widths in Tables 19.70.250 (A) (B) and (C) have been established in accordance with the best available science. The buffer widths must be determined based on the category of wetland, surrounding land use intensity, and the habitat score as assigned by a qualified wetland professional using the most up to date version of the Washington State Wetland Rating System for Western Washington.
1. **Measurement of Wetland Buffers.** All buffers must be measured horizontally from edge of the wetland boundary as surveyed in the field. The width of the wetland buffer must be determined according to Tables 16.55.340(B), (C) and (D).
  2. **Buffer Standards.** The buffer standards required by this chapter presume the existence of a dense vegetation community in the buffer adequate to protect the wetland functions and values. When a buffer lacks adequate vegetation, the ~~decision-maker~~Decision-maker may increase the standard buffer, require buffer planting or other enhancements, and/or deny a proposal for buffer reduction or buffer averaging.
- B. For the purposes of buffer determination below, Land Use Intensity rating is as follows:

**Table 19.70.235 (A)**

|                                    |                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>High Land Use Intensity</b>     | Land use that includes the following uses or activities: commercial, industrial, institutional, retail sales, nonresidential use in zones where the primary intent is residential, <u>high density all</u> residential zones (R4, R4A, <u>R3, R3A, R2, R2A, R1, OT</u> ), high-intensity recreation (such as golf courses, ball fields, <del>), and</del> <u>and</u> hobby farms. |
| <b>Moderate Land Use Intensity</b> | Land use that includes the following uses or activities: <u>medium density residential (R2, R2A, R3, R3A),</u> moderate-intensity open space (parks, trails, and logging roads).                                                                                                                                                                                                  |
| <b>Low Land Use Intensity</b>      | Land use that includes the following uses or activities: <u>low density residential (R1),</u> forestry (cutting of trees only), low-intensity open space (such as passive recreation and natural resources preservation), unpaved trails.                                                                                                                                         |

**Commented [CT10]:** Change to:

Land use that includes the following uses or activities: commercial, industrial, institutional, retail sales, nonresidential use in zones where the primary intent is residential, high density all residential zones (R4, R4A, R3, R3A, R2, R2A, R1, OT), high-intensity recreation (such as golf courses, ball fields, ), hobby farms.

**Commented [CT11]:** Change to:

Land use that includes the following uses or activities: moderate-intensity open space (parks, trails, and logging roads).

**Commented [CT12]:** Change to:

Land use that includes the following uses or activities: forestry (cutting of trees only), low-intensity open space (such as passive recreation and natural resources preservation), unpaved trails.

C. There are three sets of buffer standards, based on these parameters:

1. Buffer Widths for wetlands that have a high level of function for wildlife habitat as indicated by a habitat function score of 8 or 9 points on the wetland rating form:

Table 19.70.235 (B).

| Wetland Category | Buffer Width (feet) |                    |               |
|------------------|---------------------|--------------------|---------------|
|                  | High Intensity      | Moderate Intensity | Low Intensity |
| Category I       | <del>200</del> 300  | <del>150</del> 225 | 150           |
| Category II      | <del>200</del> 300  | <del>150</del> 225 | 100           |
| Category III     | 150                 | 110                | 75            |
| Category IV      | 50                  | 40                 | 25            |

Commented [CT13]: The following changes to the table:

2. Buffer Widths for wetlands that have a moderate level of function for wildlife habitat as indicated by a habitat function score of 6 or 7 points on the wetland rating form:

Table 19.70.235 (C).

| Wetland Category | Buffer Width (feet) |                    |                  |
|------------------|---------------------|--------------------|------------------|
|                  | High Intensity      | Moderate Intensity | Low Intensity    |
| Category I       | 150                 | 110                | 75               |
| Category II      | 150                 | 110                | 75               |
| Category III     | 150                 | <del>100</del> 110 | <del>60</del> 75 |
| Category IV      | 50                  | 40                 | 25               |

Commented [CT14]: Add the following section:

Reducing Buffer Widths.

1. For wetlands that score 6 points or more for habitat function, buffer widths for high intensity may be reduced to moderate intensity if both of the following criteria are met:
  - a. A relatively undisturbed, vegetated corridor at least 100 feet wide is protected between the wetland and any other relatively undisturbed area, as defined in the 2014 wetland rating system, or any other Priority Habitat as defined by the Washington State Department of Fish and Wildlife. The latest definitions of Priority Habitats and their locations are available on the WDFW web site at: <http://wdfw.wa.gov/hab/phshabs.htm>. The corridor must be protected for the entire distance between the wetland and the relatively undisturbed area or Priority Habitat by some type of legal protection such as a conservation easement. Presence or absence of a nearby habitat must be confirmed by a qualified biologist.

b. The measures in Table XX are implemented, where applicable, to minimize the impacts of the adjacent land uses.

2. For wetlands that score 3-5 habitat points, only the measures in Table 17.70.250(E) are required for the use of moderate intensity buffer widths.

3. If an applicant chooses not to apply the mitigation measures in Table 17.70.250(E), or is unable to provide a protected corridor where available, then high intensity buffer widths must be used.

Add Table : 19.70.250 (E)

3. Buffer Widths for wetlands that have a low level of function for wildlife habitat as indicated by a habitat function score of 3 to 5 points on the wetland rating form:

Table 19.70.235 (D).

| Wetland Category | Buffer Width (feet) |                    |                  |
|------------------|---------------------|--------------------|------------------|
|                  | High Intensity      | Moderate Intensity | Low Intensity    |
| Category I       | 100                 | 75                 | 50               |
| Category II      | 100                 | 75                 | 50               |
| Category III     | 80                  | 60                 | <del>50</del> 40 |
| Category IV      | 50                  | 40                 | 25               |

Formatted: Font: Not Bold

D. Reducing Buffer Widths.

1. For wetlands that score 6 points or more for habitat function, buffer widths for high intensity may be reduced to moderate intensity if both of the following criteria are met:

a. A relatively undisturbed, vegetated corridor at least 100 feet wide is protected between the wetland and any other relatively undisturbed area, as defined in the 2014 wetland rating system, or any other Priority Habitat as defined by the Washington State Department of Fish and Wildlife. The latest definitions of Priority Habitats and their locations are available on the WDFW web site at: <http://wdfw.wa.gov/hab/phshabs.htm> ). The corridor must be protected for the entire distance between the wetland and the relatively undisturbed area or Priority Habitat by some type of legal protection such as a conservation easement. Presence or absence of a nearby habitat must be confirmed by a qualified biologist.

2. The measures in Table 19.70.235(E) are implemented, where applicable, to minimize the impacts of the adjacent land uses.

3. For wetlands that score 3-5 habitat points, only the measures in Table 17.70.250(E) are required for the use of moderate intensity buffer widths.

4. If an applicant chooses not to apply the mitigation measures in Table 17.70.250(E), or is unable to provide a protected corridor where available, then high intensity buffer widths must be used

Formatted: Indent: Left: 0.13", Hanging: 0.25", No bullets or numbering

Table 19.70.235 (E)

| Disturbance       | Required Measures to Minimize Impacts                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lights            | <ul style="list-style-type: none"><li>• Direct lights away from wetland</li></ul>                                                                                                                                                                                                                                                                                                                                                                                    |
| Noise             | <ul style="list-style-type: none"><li>• Locate activity that generates noise away from wetland</li><li>• If warranted, enhance existing buffer with native vegetation plantings adjacent to noise source</li><li>• For activities that generate relatively continuous, potentially disruptive noise, such as certain heavy industry or mining, establish an additional 10' heavily vegetated buffer strip immediately adjacent to the outer wetland buffer</li></ul> |
| Toxic runoff      | <ul style="list-style-type: none"><li>• Route all new, untreated runoff away from wetland while ensuring wetland is not dewatered</li><li>• Establish covenants limiting use of pesticides within 150 ft of wetland</li><li>• Apply integrated pest management</li></ul>                                                                                                                                                                                             |
| Stormwater runoff | <ul style="list-style-type: none"><li>• Retrofit stormwater detention and treatment for roads and existing adjacent development</li><li>• Prevent channelized flow from lawns that directly enters the buffer</li><li>• Use Low Intensity Development techniques (for more information refer to the stormwater manual)</li></ul>                                                                                                                                     |

| Disturbance                                                                                                                          | Required Measures to Minimize Impacts                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Change in water regime (increase or decrease in the frequency, duration, timing, extent, depth or variability of water in a wetland) | <ul style="list-style-type: none"> <li>• Infiltrate or treat, detain, and disperse into buffer new runoff from impervious surfaces and new lawns</li> </ul>                                                                                                                                                 |
| Pets and human disturbance                                                                                                           | <ul style="list-style-type: none"> <li>• Use privacy fencing OR plant dense vegetation to delineate buffer edge and to discourage disturbance using vegetation appropriate for the ecoregion</li> <li>• Place wetland and its buffer in a separate tract or protect with a conservation easement</li> </ul> |
| Dust                                                                                                                                 | <ul style="list-style-type: none"> <li>• Use best management practices to control dust</li> </ul>                                                                                                                                                                                                           |

**A. Increasing buffer widths.** Buffer widths may be increased, on a case-by-case basis, as determined by the ~~Decision-maker~~Decision-maker. This determination must be supported by appropriate documentation showing that it is necessary to protect wetland functions and values. Documentation must include, but is not limited to, any of the following:

1. The wetland is used by a plant or animal species listed by the Federal government or the State as endangered, threatened, candidate, sensitive, monitored, or documented priority species or habitats, or the wetland is essential or outstanding habitat for those species or has unusual nesting or resting sites such as heron rookeries or raptor nesting trees; or
2. The adjacent land has slopes greater than 15 percent and is susceptible to severe erosion, and erosion-control measures will not effectively prevent adverse wetland impacts; or
3. The adjacent land has minimal vegetative cover on slopes greater than 30%. In lieu of increasing the buffer width where existing buffer vegetation is inadequate to protect the wetland functions and values, development and implementation of a wetland buffer restoration/enhancement plan in accordance with AMC 19.70.270 may be substituted.

**B. Averaging buffer widths.** The ~~Decision-maker~~Decision-maker may allow averaging of wetland buffer widths on a case-by-case basis when the critical areas report demonstrates that the following criteria are met:

Formatted: Indent: Left: 0.06", Hanging: 0.25", No bullets or numbering

~~i.a.~~ There is not a feasible alternative to the site design that could be accomplished without buffer averaging;

Formatted: Outline numbered + Level: 6 + Numbering  
Style: a, b, c, ... + Aligned at: 1.25" + Indent at: 1.5"

~~ii.b.~~ The buffer averaging does not reduce the functions or values of the wetland, either through preservation of total buffer area or enhancement of buffer areas;

~~iii.c.~~ The total area contained in the buffer area after averaging is no less than that which would be contained within the standard buffer.

~~iv.d.~~ The wetland contains variation in sensitivity due to existing physical characteristics or the character of the buffer varies in slope, soils, or vegetation, and the wetland would benefit from a wider buffer in places and would not be adversely impacted by a narrow buffer in other places;

~~v.e.~~ The buffer width at its narrowest point is not reduced to less than 75 percent of the standard width, for Category I and II. No less than 50 percent or 35 feet for Category III, and 15 feet for Category IV, whichever is greater.

~~B.~~ **C. Measurement of Wetland Buffers.** All buffers must be measured perpendicular from the wetland boundary as surveyed in the field. The buffer for a wetland created, restored, or enhanced as a compensation for approved wetland alterations must be the same as the buffer required for the category of the created, restored, or enhanced wetland.

Formatted: Indent: Left: 0.25", No bullets or numbering

~~C.~~ **D. Buffers on mitigation sites.** Buffer widths must be applied to mitigation sites consistent with the wetland ratings and buffer requirements of this chapter for subsequent development proposals based on expected category of the wetland once the mitigation actions are taken. Only fully vegetated buffers with predominantly native plants will be included in the new buffer area. Lawns, walkways, driveways, and other mowed or paved areas will not count towards the required buffer calculations.

~~D.~~ **E. Buffer Maintenance.** Except as otherwise specified or allowed in accordance with this Chapter, wetland buffers must be retained in an undisturbed or enhanced condition. In the case of compensatory mitigation sites, removal of invasive nonnative weeds is required for the duration of the mitigation bond.

Formatted: Indent: Left: 0.19", Hanging: 0.19", No bullets or numbering

~~E.~~ **F. Buffer impacts.** When buffer impacts occur, compensatory mitigation must be provided at a minimum ratio of 1:1 for the area impacted. The mitigation must occur on the same site when feasible or within the same wetland system preferably. The mitigation must ensure that the wetland functions and values are not diminished due to the buffer impacts.

Formatted: Indent: Left: 0.31", No bullets or numbering

~~F.~~ **G. Stormwater management facilities.** Stormwater management facilities may be allowed in Category III and IV wetland buffers if they meet all of the criteria identified below:

~~1.4.~~ The wetland is classified as a Category III or a Category IV wetland with a habitat score of 3-5 points or less, and

- ~~2.5.~~ There will be “no net loss” of functions and values of the wetlands, and
- ~~3.6.~~ The wetland does not contain a breeding population of any native amphibian species, and
- ~~4.7.~~ The hydrologic functions of the wetland can be improved as outlined in questions 3, 4, 5 of Chart 4 and questions 2, 3, 4 of Chart 5 in the “Guide for Selecting Mitigation Sites Using a Watershed Approach,” (available here: <http://www.ecy.wa.gov/biblio/0906032.html>); or the wetland is part of a priority restoration plan that achieves restoration goals identified in a Shoreline Master Program or other local or regional watershed plan;
- ~~5.8.~~ The wetland lies in the natural routing of the runoff, and the discharge follows the natural routing, and
- ~~6.9.~~ All regulations regarding stormwater and wetland management are followed, including but not limited to local and state wetland and stormwater codes, manuals, and permits, and
- ~~7.10.~~ Modifications will require permits. Existing functions and values that are lost would have to be compensated/replaced through an approved mitigation plan.

**G. H. Setbacks from buffers.** Buildings, structures, paving, and other hard surfacing must be set back a minimum distance of 10 feet from the edge of the wetland buffer, or edge of the wetland if no buffer is required, unless otherwise determined by the ~~Decision-maker~~ **Decision-maker** that a smaller distance would meet the intent of this subsection. This setback is to avoid conflicts with tree branches and/or critical root zones of trees that are in the buffer or will be planted in the buffer. The following may be allowed in the building setback from the buffer if they do not cause damage to the critical root zone of trees in the buffer:

1. Landscaping;
2. Uncovered decks, roof eaves and overhangs, unroofed stairways and steps;
3. Pervious ground surfaces, such as driveways, patios, and parking may be allowed; provided that it is engineered as a ~~pervious-permeable pavement~~ **pervious-permeable pavement** system as defined in AMC ~~19.12.020~~ **19.12.020**. Such improvements may be subject to the requirements in AMC ~~19.76~~ **19.76**, Stormwater Management.

**H. I. Functionally Separated and Isolated Buffers.** Consistent with the definition of “buffer” AMC 19.12.020, areas that are functionally isolated and physically separated from a wetland due to existing, legally established roadways, railroads or other legally established structures or paved areas eight feet or more in width that occur between the area in question and the wetland must be considered physically isolated and functionally separated buffer. Once determined by the ~~Decision-maker~~ **Decision-maker**, based on a submitted critical area report, to be a physically separated and functionally isolated wetland buffer, development proposals are allowed in these areas.

#### **19.70.240 Wetlands - Critical areas report additional requirements**

**A. Additional Report Contents for Wetlands.** In addition to the minimum report contents required per AMC 19.70.125 wetland reports must also include;

Formatted: Indent: Left: 0.19", Hanging: 0.19", No bullets or numbering

Formatted: Indent: Left: 0", Hanging: 0.25", No bullets or numbering

1. For each wetland identified on site and off site within 300 feet of the project site provide: the wetland rating, including a description of and score for each function, per wetland ratings (AMC 19.70.210) required buffers (AMC 19.70.250); hydrogeomorphic classification; wetland acreage based on a professional survey from the field delineation (acreages for on-site portion and entire wetland area including off-site portions); Cowardin classification of vegetation communities; habitat elements; soil conditions based on site assessment and/or soil survey information; and to the extent possible, hydrologic information such as location and condition of inlet/outlets (if they can be legally accessed), estimated water depths within the wetland, and estimated hydroperiod patterns based on visual cues (e.g., algal mats, drift lines, flood debris, etc.). Provide acreage estimates, classifications, and ratings based on entire wetland complexes, not only the portion present on the proposed project site;
2. A discussion of the potential impacts to the wetland(s) associated with anticipated hydroperiod alterations from the project;
3. A description of the proposed actions, including an estimation of acreages of impacts to wetlands and buffers based on the field delineation and survey and an analysis of site development alternatives, including a no-development alternative;
4. An assessment of the probable cumulative impacts to the wetlands and buffers resulting from the proposed development;
5. A description of reasonable efforts made to apply mitigation sequencing pursuant to AMC 19.70.130 to avoid, minimize, and mitigate impacts to critical areas and a discussion of measures, including avoidance, minimization, and compensation, proposed to preserve existing wetlands and restore any wetlands that were degraded prior to the current proposed land-use activity;
6. A conservation strategy for habitat and native vegetation that addresses methods to protect and enhance on-site habitat and wetland functions; and
7. An evaluation of the functions of the wetland and adjacent buffer. Include reference for the method used and data sheets.

B. **Additional Information.** When appropriate due to the proposed impacts or the project area conditions, the ~~Decision-maker~~[Director](#) may also require the critical area report to include:

1. A request for consultation with the Washington State Department of Fish and Wildlife (DFW), Washington State Department of Ecology (Ecology), local Native American ~~Indian~~ tribes, and/or other appropriate agency;
2. Copies of the Joint Aquatic Resource Permit Application (JARPA) and related approvals, such as a Hydraulic Project Approval (HPA) from the Washington Department of Fish and Wildlife (WDFW), when applicable to the project; and
3. Detailed surface and subsurface hydrologic features both on and adjacent to the site.

#### 19.70.245 Wetlands – Compensatory mitigation performance standards and requirements.

**A. Compensatory Mitigation Plan.** When a project involves wetland and/or buffer impacts, a compensatory mitigation plan must be included as part of the required critical area report. Compensatory wetland mitigation plans must meet the minimum requirements [of](#) AMC 19.70.140 and demonstrate compliance with [ACMC](#) 19.70.135. Full guidance can be found in Wetland Mitigation in Washington State – Part 2: Developing Mitigation Plans (Version 1) (Ecology Publication No. 06-06-011b, March 2006, or as revised). The mitigation plan must meet the following additional standards:

1. Description of the existing wetland and buffer areas proposed to be impacted. Include acreage (or square footage), water regime, vegetation, soils, landscape position, surrounding land uses, and functions. Also describe impacts in terms of acreage by Cowardin classification, hydrogeomorphic classification, and wetland rating, based on wetland ratings (AMC 19.70.210(B));
2. Description of the compensatory mitigation site, including location and rationale for selection. Include an assessment of existing conditions: acreage (or square footage) of wetlands and uplands, water regime, sources of water, vegetation, soils, landscape position, surrounding land uses, and functions. Estimate future conditions in this location if the compensation actions are not undertaken (i.e., how would this site progress through natural succession);
3. A description of the proposed actions for compensation of wetland and upland areas affected by the project. Include overall goals of the proposed mitigation, including a description of the targeted functions, hydrogeomorphic classification, categories of wetlands, and mitigation ratios applied (if ratio approach used);
4. A description of the proposed mitigation construction activities, construction/installation notes, and timing of activities;
5. A discussion of ongoing management practices that will protect wetlands after the project site has been developed, including proposed monitoring and maintenance programs (for remaining wetlands and compensatory mitigation wetlands);
6. Proof of establishment of notice on title for the wetlands and buffers on the project site, including the compensatory mitigation areas; and
7. The scaled plan sheets for the compensatory mitigation must contain, at a minimum
  - a. An accurate depiction of the existing wetland and buffers, proposed areas of wetland and/or buffer impacts, location of proposed wetland and/or buffer compensation actions;
  - b. Existing topography, ground-proofed, at two-foot contour intervals in the zone of the proposed compensation actions if any grading activity is proposed to create the compensation area(s). Also existing cross-sections of

on-site wetland areas that are proposed to be impacted and cross-section(s) (estimated one-foot intervals) for the proposed areas of wetland or buffer compensation;

- c. Surface and subsurface hydrologic conditions, including an analysis of existing and proposed hydrologic regimes for enhanced, created, or restored compensatory mitigation areas. Also, illustrations of how data for existing hydrologic conditions were used to determine the estimates of future hydrologic conditions;
- d. Conditions expected from the proposed actions on site, including future hydrogeomorphic types, vegetation community types by dominant species (wetland and upland), and future water regimes;
- e. Required wetland buffers for existing wetlands and proposed compensation areas. Also, identify any zones where buffers are proposed to be reduced or enlarged outside of the standards identified in this chapter;
- f. A plant schedule for the compensation area, including all species by proposed community type and water regime, size and type of plant material to be installed, spacing of plants, typical clustering patterns, typical plant installation details and notes, total number of each species by community type, timing of installation; and
- g. Performance standards (measurable standards reflective of years post-installation) for upland and wetland communities, monitoring plan, contingency plan, and maintenance schedule, and actions. Standards for success must be established based on the performance standards identified and the functions and values being mitigated based on the guidance in Wetland Mitigation in Washington State – Part 2: Developing Mitigation Plans (Version 1) (Ecology Publication No. 06-06-011b, March 2006, or as revised).

#### **B. Requirements for Compensatory Mitigation.**

- 1. Compensatory mitigation for alterations to wetlands may be used only for impacts that cannot be avoided or minimized, except as otherwise exempted in this chapter AMC 19.70.240, and must achieve equivalent or greater biologic functions. Compensatory mitigation plans must be consistent with Wetland Mitigation in Washington State – Part 2: Developing Mitigation Plans (Version 1), (Ecology Publication No. 06-06-011b, March 2006, or as revised).
- 2. Mitigation ratios must be consistent with subsection I of this section.
- 3. Mitigation requirements may also be determined using the credit/debit tool described in “Calculating Credits and Debits for Compensatory Mitigation in Wetlands of Western

Washington: Final Report March 2012" (Ecology Publication No. 10-06-011, March 2012, or as revised) consistent with subsection H of this section.

**C. Compensating for Lost or Impacted Wetland Functions.** Compensatory mitigation must address the functions and values affected by the proposed project, with an intention to achieve functional equivalency or improvement of functions and values. The goal for the compensatory mitigation must be to provide similar wetland functions and values as those lost, except when either:

1. The lost wetland provides minimal functions and values, and the proposed compensatory mitigation action(s) will provide equal or greater functions and values or will provide functions and values shown to be limiting within a watershed through a formal Washington State watershed assessment plan or protocol; or
2. Out-of-kind replacement of wetland type or functions and values will best meet watershed goals formally identified by the City, such as replacement of historically diminished wetland types.

**D. Preference of Mitigation Actions.** Methods to achieve compensation for wetland functions and values must be approached in the following order of preference:

1. **Restoration.** The manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning natural or historic functions to a former or degraded wetland. Restoration of wetlands includes re-establishment and rehabilitation.
  - a. **Re-establishment.** Returning natural or historic functions to a former wetland. Re-establishment results in a gain in wetland acres (and functions). Activities could include removing fill material, plugging ditches, or breaking drain tiles.
  - b. **Rehabilitation.** Repairing natural or historic functions of a degraded wetland. Rehabilitation results in a gain in wetland function but does not result in a gain in wetland acres. Activities could involve breaching a dike to reconnect wetlands to a floodplain or return tidal influence to a wetland.
2. **Creation.** Creation (establishment) of wetlands on disturbed upland sites, such as those with vegetative cover consisting primarily of nonnative species. This should be attempted only when there is an adequate source of water and it can be shown that the surface and subsurface hydrologic regime is conducive to the wetland community that is anticipated in the design.
3. **Enhancement.** Enhancement of significantly degraded wetlands in combination with restoration or creation. Enhancement alone will result in a loss of wetland acreage and is less effective at replacing the functions and values lost. Enhancement should be part of a mitigation package that includes replacing the impacted area and meeting appropriate ratio requirements.

4. **Preservation.** Preservation of high-quality, at-risk wetlands as compensation is generally acceptable when done in combination with restoration, creation, or enhancement; provided, that a minimum of 1:1 acreage replacement is provided by reestablishment or creation. Preservation of high-quality, at-risk wetlands and habitat may be considered as the sole means of compensation for wetland impacts when the following criteria are met:
  - a. Proposed wetland impacts will not have a significant adverse impact on habitat for listed fish, or other ESA-listed species;
  - b. There is no net loss of habitat functions within the watershed or basin;
  - c. Mitigation ratios for preservation as the sole means of mitigation must generally start at 20:1. Specific ratios should depend upon the significance of the preservation project and the quality of the wetland resources lost;
  - d. The impact area is small (generally less than one-half acre) and/or impacts are occurring to a low-functioning system (Category III or IV wetland); and
  - e. All preservation sites must include buffer areas adequate to protect the habitat and its functions from encroachment and degradation.
5. **Wetland Bank or Advanced Wetland Mitigation.** For future use since no current banks have a service area in Anacortes.

**E. Type and Location of Compensatory Mitigation.** Unless it is demonstrated that a higher level of ecological functioning would result from an alternative mitigation approach, compensatory mitigation for ecological functions should be either in kind and on site, or in kind and within the same stream reach, sub-basin, or drift cell (if estuarine wetlands are impacted). Compensatory mitigation actions must be conducted within the same sub-basin or on the site of the alteration, except when the following apply:

1. The conditions in AMC 19.70.270(B) are met.
2. There are no reasonable opportunities on site or within the sub-basin (e.g., on-site options would require elimination of high-functioning upland habitat), or opportunities on site or within the sub-basin do not have a high likelihood of success based on a determination of the capacity of the site to compensate for the impacts. Considerations should include:
  - a. Anticipated replacement ratios for wetland mitigation;
  - b. Buffer conditions and proposed widths;
  - c. Available water to maintain anticipated hydrogeomorphic classes of wetlands when restored; and
  - d. Proposed flood storage capacity, and potential to mitigate riparian fish and wildlife impacts (such as connectivity);

- e. Off-site mitigation has a greater likelihood of providing equal or improved wetland functions than the impacted wetland;
- f. Off-site locations must be in the same sub-basin, unless watershed goals for water quality, flood storage or conveyance, habitat, or other wetland functions have been established by the City and strongly justify location of mitigation at another site; and
- g. The design for the compensatory mitigation project needs to be appropriate for its location (i.e., position in the landscape). Therefore, compensatory mitigation should not result in the creation, restoration, or enhancement of an atypical wetland. An atypical wetland refers to a compensation wetland (e.g., created or enhanced) that does not match the type of existing wetland that would be found in the geomorphic setting of the site (i.e., the water source(s) and hydroperiod proposed for the mitigation site are not typical for the geomorphic setting). Likewise, it should not provide exaggerated morphology or require a berm or other engineered structures to hold back water. For example, excavating a permanently inundated pond in an existing, seasonally saturated or inundated wetland is one example of an enhancement project that could result in an atypical wetland. Another example would be excavating depressions in an existing wetland on a slope, which would require the construction of berms to hold the water.

**F. Wetland Mitigation Banks.** Credits from a wetland mitigation bank certified under [WAC 173-700](#) may be used to compensate for impacts located within the service area specified in the mitigation bank instrument, if:

- 1. The proposal would provide appropriate compensation for the proposed impacts; and
- 2. The impact site is located in the service area of the bank.
- 3. The proposed use of credits is consistent with the terms and conditions of the certified mitigation bank instrument.
- 4. Replacement ratios using bank credits are consistent with replacement ratios specified in the certified mitigation bank instrument.

**G. In-Lieu Fee Mitigation.** Credits from an approved in-lieu fee (ILF) program may be used when all of the following apply:

- 1. The ~~Decision-maker~~[Decision-maker](#) determines that it would provide environmentally appropriate compensation for the proposed impacts.
- 2. The proposed use of credits is consistent with the terms and conditions of the approved ILF program instrument.
- 3. Projects using ILF credits must have debits associated with the proposed impacts calculated by the applicant's qualified wetland professional using the credit assessment method specified in the approved instrument for the ILF program.
- 4. The impacts are located within the service area specified in the approved ILF instrument.

**H. Permittee-responsible mitigation.** This type of mitigation is defined in 33 CFR 332 as “an aquatic resource restoration, establishment, enhancement and/or preservation activity undertaken by the permittee (or an authorized agent or contractor) to provide compensatory mitigation for which the permittee retains full responsibility.” The permittee performs the mitigation either before the project impact occurs and before any project impact permit is issued (Advance Permittee-Responsible Mitigation) or at the same time as the project impact is occurring after the project impact permit is issued (Concurrent Permittee-Responsible Mitigation). The permittee is ultimately responsible for implementation and success of the mitigation. For advance mitigation, the permittee generates mitigation credits that may be used to compensate for future wetland or buffer impacts. Only the permittee may use the advance mitigation credits. Permittee-responsible mitigation may occur at the site of the permitted impacts or at an off-site location within the same watershed. Permittee-responsible mitigation must be used only if the applicant’s qualified wetland professional demonstrates to the [Decision-maker’s approval authority’s](#) satisfaction that the proposed approach is ecologically preferable to use of a bank or ILF program, consistent with the criteria in this section.

**I. Alternative Mitigation Plan.** The ~~Decision-maker~~[Decision-maker](#) may approve an alternative wetland mitigation plan that is based on best available science. Proposed alternative mitigation plans must provide an equivalent or better level of protection of wetland functions and values than would be provided by the strict application of this chapter.

1. The following will be considered in the approval of an alternative mitigation plan:

- a. The plan uses a watershed approach consistent with [Selecting Wetland Mitigation Sites Using a Watershed Approach \(Western Washington\)](#) (Ecology Publication #09-06-032, Olympia, WA, December 2009).
- b. Creation or enhancement of a larger system of natural areas and open space is preferable to the preservation of many individual small habitat areas.
- c. Mitigation according to Section D is not feasible due to site constraints including but not limited to parcel size, stream type, wetland category, or geologically hazardous areas.
- d. There is a clear potential for success of the proposed compensation at the identified site.
- e. The Plan must contain clear and measurable standards for achieving compliance with the specific provisions of the plan, consistent with AMC 19.70.135.
- f. The plan must be reviewed and approved as part of the overall approval of the proposed use.
- g. A wetland of a different type may be justified based on regional needs or functions and values; the replacement ratios may not be reduced or eliminated unless the reduction results in a preferred environmental alternative.

- h. Mitigation guarantees must meet the minimum requirements as outlined in AMC 19.70.160.
  - i. Qualified professionals in each of the critical areas addressed must prepare the plan.
  - j. The City may consult with agencies with expertise and jurisdiction over the critical areas during the review to assist with analysis and identification of appropriate performance measures that adequately safeguard critical areas.
- J. **Wetland Mitigation Ratios.** The ratios below are based on the assumption that the rehabilitation or enhancement actions implemented represent the average degree of improvement possible for the site. Proposals to implement more effective rehabilitation or enhancement actions may result in a lower ratio, while less effective actions may result in a higher ratio. The distinction between rehabilitation and enhancement is not clear-cut. Instead, rehabilitation and enhancement actions span a continuum. Proposals that fall within the gray area between rehabilitation and enhancement will result in a ratio that lies between the ratios for rehabilitation and the ratios for enhancement.

**Table 19.70.245 – Wetland Mitigation Ratios**

| Category and Type of Wetland              | Creation or Reestablishment | Rehabilitation Only                           | Re-Est or Creation (R/C) and Re-hab (RH) | Re-Est or Creation (R/C) and Enhancement (E) | Enhancement Only |
|-------------------------------------------|-----------------------------|-----------------------------------------------|------------------------------------------|----------------------------------------------|------------------|
| Category I Mature Forested                | 6:1                         | 12:1                                          | 1:1 R/C & 10:1 RH                        | 1:1 R/C & 20:1 E                             | 24:1             |
| Category I – based on score for functions | 4:1                         | 8:1                                           | 1:1 R/C & 6:1 RH                         | 1:1 R/C & 12:1 E                             | 16:1             |
| Category I Natural Heritage Site          | Not allowed                 | 6:1 Rehabilitation of a Natural Heritage Site | Not allowed                              | Not allowed                                  | Case-by-case     |
| Category I Bog                            | Not allowed                 | 6:1 Rehabilitation of a bog                   | Not allowed                              | Not allowed                                  | Case-by-case     |
| Category I Estuarine                      | Case-by-case                | 6:1 Rehabilitation of an                      | Case-by-case                             | Case-by-case                                 | Case-by-case     |

| Category and Type of Wetland | Creation or Reestablishment | Rehabilitation Only | Re-Est or Creation (R/C) and Re-hab (RH) | Re-Est or Creation (R/C) and Enhancement (E) | Enhancement Only |
|------------------------------|-----------------------------|---------------------|------------------------------------------|----------------------------------------------|------------------|
|                              |                             | estuarine wetland   |                                          |                                              |                  |
| Category II                  | 3:1                         | 6:1                 | 1:1 R/C & 4:1 RH                         | 1:1 R/C & 8:1 E                              | 12:1             |
| Category III                 | 2:1                         | 4:1                 | 1:1 R/C & 2:1 RH                         | 1:1 R/C & 4:1 E                              | 8:1              |
| Category IV                  | 1.5:1                       | 3:1                 | 1:1 R/C & 1:1 RH                         | 1:1 R/C & 2:1 E                              | 6:1              |

- K. **Buffer Mitigation Ratios.** Impacts to buffers must be mitigated at a 1:1 ratio. Compensatory buffer mitigation must replace those buffer functions lost from development.
- L. **Mitigation Performance Standards.** Wetland mitigation plans must be consistent with AMC 19.70.130 Mitigation requirements and 19.70.135 Mitigation plan requirements and Wetland Mitigation in Washington State, Part 1: Agency Policies and Guidance (Version 1, Ecology Publication #06-06-011a), or as amended, and best available science.
- M. **Minimum Standards.** The design standards in this section must be incorporated into mitigation plans submitted to the City for impacts to wetlands and/or wetland buffers. The following standards apply to any mitigation proposed within Category I, II, III and IV wetlands and their buffers. Modifications to these design standards consistent with the guidance in Wetland Mitigation in Washington State – Part 2: Developing Mitigation Plans (Version 1) (Ecology Publication No. 06-06-011b, March 2006, or as revised) may be considered for approval by the ~~Decision-maker~~[Decision-maker](#) as alternatives to the following standards:
1. Plants native to the region (not introduced, non-native or exotic species) must be used.
  2. Plant species selection must be consistent with the existing or projected hydrologic regime, including base water levels and stormwater event fluctuations.
  3. Plant species selection must be consistent with the site environmental conditions such as slope, aspect, soils and exposure to sun, wind and rain.
  4. Plants should be commercially available or available from local sources.
  5. Native plant species high in food and cover value for fish and wildlife should be prioritized, as appropriate for the site.

6. Plant selection must be approved by a qualified professional.
7. The following standards apply to wetland design and construction:
  - a. For wetland creation sites, preliminary investigations of existing hydrology at the site must be completed to confirm that the site has adequate source hydrology (e.g., high groundwater, precipitation or riverine flooding) to support wetland conditions.
  - b. Water depth in areas of seasonal or occasional inundation must not exceed three feet (0.914 meters), unless the proposed mitigation is compensating for impacts to unvegetated/open water areas.
  - c. If creating or rehabilitating a slope wetland, the grade or slope within the wetland must not exceed 6 percent, unless otherwise approved by the ~~Decision-maker~~[Decision-maker](#).
  - d. Slopes within the wetland contributing basin and the buffer zone must not be steeper than 3:1 (horizontal to vertical).
  - e. The wetland (excluding the buffer area) should not contain more than 20 percent unvegetated/open water areas as measured at the seasonal high water mark, unless the mitigation is compensating for vegetated.
  - f. Site soils must be free of contamination and/or hazardous materials, and must have adequate organic content and porosity to support the proposed native plant community.
  - g. Planting densities and placement of plants should be determined by a qualified professional and shown on the design plans.
8. The planting plan must be approved by the City.
9. Stockpiling soil and construction materials should be confined to upland areas and contract specifications should limit stockpiling of earthen materials to durations in accordance with City clearing and grading standards, unless otherwise approved by the City.
10. Planting instructions must be submitted which describe placement, diversity, and spacing of seeds, tubers, bulbs, rhizomes, sprigs, plugs, and transplanted stock.
11. Controlled release fertilizer (if required) must be used in upland areas only (buffers and other non-wetland areas) and must be installed into the planting hole only at the time of planting. No fertilizer must be applied to the ground surface.
12. An irrigation system must be installed or watering afforded by trucks or hoses to provide water for installed plants and seeded areas to supplement rainfall to ensure

that plants receive approximately 0.5 inches of water per week during the dry season of the first two years after plant installation.

13. All construction specifications and methods must be approved by a qualified professional and the City.
14. Construction management provided must be provided by a qualified professional. Ongoing work on site must be inspected by the City.

## **PART 3: FISH AND WILDLIFE HABITAT CONSERVATION AREAS**

### **19.70.310. Fish and wildlife habitat – Description and Purpose**

- A. Fish and wildlife habitat conservation areas are lands managed for maintaining populations of species in suitable habitats within their natural geographic distribution so that the habitat available is sufficient to support viable populations over the long term and isolated subpopulations are not created. In addition to their intrinsic value, certain species of fish and wildlife represent important historic, cultural, recreational and economic resources.
- B. It is the purpose of this Chapter to protect fish and wildlife populations and their associated habitats and provide special consideration to conservation or protection measures necessary to preserve or enhance anadromous species.

### **19.70.315 Fish and wildlife habitat – Designation.**

- A. Fish and Wildlife Habitat Conservation Areas (FWHCAs) are designated as follows:

1. ~~Areas with which endangered, threatened, and sensitive species listed by the federal government or the State of Washington have a primary association;~~Critical saltwater habitats, which include all kelp beds, eelgrass beds, spawning and holding areas for forage fish, such as herring, smelt and sand lance; subsistence, commercial and recreational shellfish beds; mudflats, intertidal habitats with vascular plants, and areas with which priority species have a primary association.
2. ~~Commercial and recreational shellfish areas, including public and private tidelands suitable for shellfish harvest and shellfish protection districts established pursuant to RCW 90.72;~~
3. ~~Kelp and eelgrass beds and herring and smelt spawning areas;~~
- 4-2. Naturally occurring ponds under 20 acres with submerged aquatic beds that provide fish or wildlife habitat as further defined in WAC 365-190-130(4)(e);
- 5-3. Waters of the State, including streams as classified in WAC 222-16-030;

Formatted: Font: Not Bold, Not Italic

Formatted: Font: Not Bold, Not Italic

~~6.4.~~ Lakes, ponds, streams, and rivers planted with game fish by a governmental or tribal entity;

~~7.5.~~ Areas with which anadromous fish species have a primary association;

~~8.6.~~ State natural area preserves, natural resource conservation areas, and state wildlife areas as established by WA DNR;

~~9.7.~~ Areas of rare plant species and high quality ecosystems as identified by the Washington State Department of Natural Resources through the Natural Heritage Program in Chapter [79.70](#) RCW.

~~10.8.~~ State priority habitats and areas associated with State priority species defined and listed by the State Department of Fish and Wildlife in the Priority Habitats and Species List Updated January 2019. Priority habitats and species known to be identified and mapped by WDFW (<http://apps.wdfw.wa.gov/phsontheweb/>) in Anacortes include, but may not be limited to, the following:

- a. Biodiversity areas;
- b. Bald eagle habitat protected pursuant to the Federal Bald and Golden Eagle Protection Act;
- c. Chinook/fall chinook salmon;
- d. Coho salmon;
- e. Great blue heron nest sites and breeding areas;
- f. Osprey nest sites;
- g. Peregrine falcon nest sites and breeding areas;
- h. Purple martin breeding areas;
- i. Resident coastal cutthroat trout;
- j. Winter steelhead trout;
- k. Water fowl concentrations.

~~11.9.~~ The following Habitats and Species of Local Importance have been designated by the City:

- a. The Anacortes Community Forestlands.
- b. The March Point Heronry.
- c. The one and one-half acre "Park Reserve" at Cap Sante bounded by 3<sup>rd</sup> Street, East Park Drive, and Curtis Drive.
- d. [Ship Harbor Wetland.](#)

Commented [CT15]: Add:

Add the following wetland for extra habitat protections, in replace of the regionally/locally significant wetland provision:

- d. Ship Harbor Wetland
- e. Cannery Pond Wetland
- f. Category II wetlands within the watersheds of Little Cranberry Lake, Whistle Lake, and Heart Lake and with seasonal surface water connections.
- g. Smiley's Bottom Wetland

e. Cannery Pond Wetland.

f. Category II wetlands within the watersheds of Little Cranberry Lake, Whistle Lake, and Hearth Lake and with seasonal surface water connections.

e.g. Smiley's Bottom Wetland.

- B. In addition to the FWHCAs identified in Subsection (A)(11) of this section, additional habitats and species of local importance may be designated by the City using the following process:
1. Designation process. The city may consider nominations for habitat areas and species to be designated as locally important on an annual basis as part of the annual comprehensive plan and development regulation update process, based on the following criteria:
    - a. Local populations of native species that are in danger of extirpation based on existing trends, likely to become endangered, or are vulnerable or declining;
    - b. The habitat represents either a high quality native habitat, or the habitat has a high potential to recover to a suitable condition and which is of limited availability, is highly vulnerable to alteration, or provides landscape connectivity which contributes to the integrity of the surrounding landscape;
    - c. The species or habitat has recreation, commercial, game, tribal, or other intrinsic value;
    - d. Long-term persistence of a species is dependent on protection, maintenance, and/or restoration of the nominated habitat;
    - e. Protection by other county, state, or federal policies, laws, regulations, or non-regulatory tools is not adequate to prevent degradation of the species or habitat; and
    - f. Without protection, there is a likelihood that the species or habitat will be diminished.
  2. The nomination must indicate whether specific habitat features are to be protected (for example, nest sites, breeding areas, and nurseries) or whether the habitat or ecosystem is being nominated in its entirety.
  3. The nomination may include management strategies for the species or habitats, which must be supported by best available science. Where restoration of habitat is proposed, a specific plan for restoration must be provided.

- C. All areas within the city meeting one or more of these criteria, regardless of any formal identification, are hereby designated critical areas and are subject to the provisions of this chapter.

#### 19.70.320 Fish and wildlife habitat – Mapping.

- A. **Mapping.** The approximate location and extent of some FWHCA's are shown in the data layers maintained in the City of Anacortes geographic information system (GIS). In addition, the following maps and inventories are hereby adopted by reference, as amended:
  - 1. [Washington Department of Fish and Wildlife Priority Habitat and Species maps](#);
  - 2. Washington Department of Natural Resources, [Official Water Type Reference maps](#);
  - 3. Washington Department of Natural Resources [Puget Sound Intertidal Habitat Inventory maps](#);
  - 4. Washington Department of Natural Resources [Shore Zone inventory](#);
  - 5. Washington Department of Natural Resources [Natural Heritage Program mapping data](#);
  - 6. Washington Department of Health Annual [Inventory of Shellfish Harvest Areas](#);
  - 7. Anadromous and resident fish distribution maps contained in the habitat limiting factors reports published by the Washington Conservation Commission and others;
  - 8. Washington Department of Natural Resources State Natural Area Preserves and Natural Resource Conservation Area maps; and
  - 9. NOAA Northwest Region Critical Habitat Mapper or equivalent source:  
<http://www.nmfs.noaa.gov/pr/species/criticalhabitat.htm>
- B. **Reference Only.** The maps and resources cited above are to be used as a guide for the City of Anacortes Planning, Community & Economic Development Department, project applicants, and/or property owners and may be continuously updated as new critical areas are identified. They are a reference and do not provide a final critical area designation.

#### 19.70.325 Fish and wildlife habitat – General Development Standards for all FWHCA's.

- A. All new development activities and uses are prohibited from habitat conservation areas and their buffers except in accordance with this Chapter [unless within shoreline jurisdiction and hereby regulated by the AMC 19.72 Shoreline Regulations and Shoreline Master Program.](#) FWHCA's or their buffers may be altered only if the proposed alteration of the habitat or the mitigation proposed does not degrade the functions and values of the habitat.
- B. **Exemptions.** Exemptions to this chapter are listed in the provisions established in AMC 19.70.035 Exemption Activities.

- C. Approvals and the Best Available Science.** Any approval of alterations or impacts to a FWHCA area must be supported by the best available science as described in the required Critical Area Report.
- D. Approvals of Activities may be conditioned.** The ~~decision-maker~~[Decision-maker](#) may condition approvals of activities allowed within or adjacent to a fish and wildlife habitat conservation area as necessary to minimize or mitigate any potential adverse impacts. Conditions will be based on the best available science and may include, but are not limited to, the following:
1. Establishment of buffers;
  2. Preservation of important vegetation and/or habitat features such as snags and downed wood specific to the priority wildlife species in the fish and wildlife habitat conservation area;
  3. Limitation of access to the habitat area, including fencing to deter unauthorized access;
  4. Seasonal restriction of construction activities;
  5. Establishment of a duration and timetable for periodic review of mitigation activities; and
  6. Requirement of a performance bond, when necessary, to ensure completion and success of proposed mitigation.
- E. Seasonal Restrictions.** When a species is more susceptible to adverse impacts during specific periods of the year, seasonal restrictions may apply. Larger buffers may be required and activities may be further restricted during the specified season.
- F. Subdivisions.** The subdivision and short subdivision of land in FWHCA's and associated buffers is subject to the following:
1. Land that is located wholly within a FWHCA or its buffer may not be subdivided;
  2. Land that is located partially within a FWHCA may be subdivided only if an accessible and contiguous portion of each new lot that meets the minimum lot size requirements for the zone is located outside of the FWHCA and its buffer.
  3. Access roads and utilities serving a proposed subdivision may be permitted within the FWHCA and associated buffers only if the applicant's qualified professional(s) demonstrate, and the ~~Decision-maker~~[Decision-maker](#) determines, that no other feasible alternative exists, all unavoidable impacts are fully mitigated, and the use is consistent with this chapter.
- G. Non-indigenous species.** No plant, wildlife, or fish species not indigenous to Fidalgo Island may be introduced to a FWHCA unless authorized by a state or federal permit approval.

#### 19.70.330 Fish and wildlife habitat – Specific Standards for Streams

**A. Typing.** Stream types must be classified according to WAC 222-16-030. Stream classifications must include the following:

1. Type F streams are those that provide fish habitat;
2. Type Np streams are perennial waters that do not contain fish habitat; and
3. Type Ns streams are seasonal waters that do not contain fish habitat, but are physically connected by an above-ground channel system to Type F, or Np waters.
4. In the case that available information on stream typing is unclear, stream typing will be performed by a qualified professional, provided by the applicant, using a site visit, mapping, and all available information.

**B. Required Buffer Areas.** Protective riparian buffers must be required to preserve stream/riparian functions and values. The purpose of riparian buffers is to protect riparian functions that influence in-stream and near-stream habitat quality

1. **Measurement of Stream Buffers.** Stream buffers are measured from the ordinary high water mark (OHWM), or the top of the bank if the OHWM cannot be determined. Buffers must be measured with rounded ends where streams enter or exit piped segments. Piped stream setbacks should be measured from the centerline of the pipe.
2. **Standard Stream Buffer Widths.** Buffer widths must reflect the sensitivity of the stream type, the risks associated with development and, in those circumstances permitted by these regulations, the type and intensity of human activity and site design proposed to be conducted on or near the stream area. The following standard buffers are established for streams:

**Table 19.70.300 Stream Buffers**

| DNR Water Type<br>(WAC 222-16-030)                                                                                                                                                                                                               | Standard Buffer Width |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| <b>Type F</b><br>Streams that are known to be used by fish, or meet the physical criteria to be potentially used by fish.                                                                                                                        | 50 feet               |
| <b>Type Np</b><br>Streams that have year round flow and do not meet the physical criteria of a Type F. This also includes streams that have been proven not to contain fish using methods described in Forest Practices Board Manual Section 13. | 50 feet               |
| <b>Type Ns</b>                                                                                                                                                                                                                                   | 50 feet               |

|                                                                                                                                                                                                                                                                  |         |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| Streams that do not have surface flow during at least some portion of the year, and do not meet the physical criteria of a Type F stream.                                                                                                                        |         |
| <b>Piped Streams and Roadside Ditched Segments</b><br>Those segments of streams, regardless of their type, that are fully enclosed in an underground pipe or culvert, or conveyed through a public roadside ditch as part of the City stormwater infrastructure. | 10 feet |

3. **Increased Stream Buffer Widths.** The stream buffer widths may be increased by the ~~Decision~~ [Decision-maker](#) as follows:

- When the qualified professional determines that the minimum width is insufficient to prevent habitat degradation and to protect the structure and functions of the habitat area as a result of a habitat assessment required pursuant to AMC 19.70.360;
- When the frequently flooded area exceeds the minimum stream buffer width, the stream buffer must extend to the outer edge of the frequently flooded area;
- When a channel migration zone is present, the stream buffer must extend to the outer edge of the channel migration zone;
- When the habitat area is in an area of high blowdown potential, the stream buffer width must be expanded an additional 50 feet on the windward side;
- When the habitat area is within an erosion or landslide hazard area, or buffer, the stream buffer width must be the recommended distance, or the erosion or landslide hazard area or buffer, whichever is greater.

C. **Buffer Reduction Standards.** The ~~Decision-Maker~~ [Decision-maker](#) may allow the reduction of buffer widths on a case-by-case basis when the critical areas report demonstrates the following criteria are met:

- There is no feasible alternative to the site design that could be accomplished without buffer reduction;
- The total buffer width is not reduced to less than 35 feet in stretches of natural stream channel with intact native vegetation within the buffer, and the buffer reduction does not reduce the functions or values of the stream or buffer;
- The total buffer width is not reduced to less than 25 feet in stretches of modified stream channel with little to no intact native vegetation within the buffer, and the buffer reduction

plan must include an enhancement plan to increase the functions or values of the stream or buffer.

**D. Building setbacks from stream buffers.** Buildings, structures, paving, and other hard surfacing must be setback a minimum distance of 10 feet from the edge of the stream buffer unless determined by the ~~Decision-maker~~[Decision-maker](#) that a smaller distance would meet the intent of this subsection. This setback is to avoid conflicts with tree branches and/or critical root zones of trees that are in the buffer or will be planted in the buffer. The following may be allowed in the building setback from the buffer if they do not cause damage to the critical root zone of trees in the buffer:

1. Landscaping;
2. Uncovered decks, roof eaves and overhangs, unroofed stairways and steps;
3. Pervious ground surfaces, such as driveways, patios, and parking may be allowed; provided that they are engineered as a [pervious-permeable pavement](#) system as defined in AMC [19.12.020](#). Such improvements may be subject to the requirements in AMC [19.76](#), Stormwater Management.

**E. Functionally Separated and Isolated Stream Buffers.** Consistent with the definition of “buffers” in this chapter, areas that are functionally isolated and physically separated from a stream due to existing, legally established public roadways, railroads or other legally established structures or paved areas eight feet or more in width that occur between the area in question and the stream must be considered physically isolated and functionally separated stream buffers. Once determined by the ~~Decision-Maker~~[Decision-maker](#), based on a submitted critical area report, to be a physically separated and functionally isolated stream buffer, development proposals are allowed in these areas.

**F. Additional Allowed Activities in streams.** Activities, uses and alterations of streams are prohibited unless otherwise listed as exempt or allowed according to the provisions of 19.70.035, 19.70.040, and 19.70.045. No alteration to a stream buffer may be permitted unless consistent with the provisions of this section and the specific standards for development outlined below.

1. **Type F and Type Np Streams Relocation.** Relocation of Type F or Np streams may be permitted only when the proposed relocation is **part of an approved mitigation or rehabilitation/restoration plan**, and will result in equal or better habitat and water quality, and will not diminish the flow capacity of the stream. The applicant must demonstrate proper mitigation sequencing.
2. **Type Ns Streams Relocation.** Relocation of Type Ns streams may be permitted only when the proposed relocation will result in equal or better habitat and water quality, and will not diminish the flow capacity of the stream. The applicant must demonstrate proper mitigation sequencing.

3. **Stream Crossing.** Crossing of streams may be permitted, and are required to be designed to allow fish passage based on state and federal fish passage criteria.

**G. Piped Watercourses and Roadside Ditches.** It is recognized that within the urban environment many historical streams have been substantially modified to accommodate development. Many of the regulated and mapped streams within the City of Anacortes pass through natural reaches, modified reaches, piped reaches, and sometimes along manmade roadside ditches.

1. Development along piped watercourses and roadside ditched segments of regulated streams are subject to a 10 foot setback from the centerline of the stream course and is subject to the recording of a utility easement granted to the city for access and maintenance of the watercourse infrastructure.
2. The voluntary opening and restoration or rehabilitation of previously channelized, culverted, or piped streams is highly encouraged and may be approved by the ~~Decision-Maker~~[Decision-maker](#), when the following is demonstrated within a critical areas report:
  - a. The restoration will result in a net gain in FWHCA functions, including an improvement in water quality and ecological functioning;
  - b. Opened channels must be designed to support fish and wildlife habitat and uninhibited fish access, unless demonstrated to be infeasible;
  - c. A reduction to the standard buffer is allowed to a minimum of 25 ~~feet~~[feet](#), or as recommended by a qualified professional in the Critical Area Report. Measured from the Ordinary High Water Mark (OHWM) and which includes habitat improvements, and measures to prevent erosion, landslide and water quality impacts;
  - d. The proposal will not significantly increase the threat of erosion, flooding, slope stability or other hazards on the site or on adjacent properties.
  - e. The proposal must demonstrate that there conveyance will maintain the flow capacity and not create flooding elsewhere in the drainage basin.

**H. Stream Enhancement Measures.** Only those enhancement measures deemed most applicable and/or appropriate for stream channel or buffer enhancement projects will be considered in a buffer modification proposal, and must be supported by best available science and a critical area report. These include, but are not limited to:

1. Removal of fish barriers to restore accessibility to fish.
2. Enhancement of fish habitat using log structures incorporated as part of a fish habitat enhancement plan.
3. Enhancement of fish and wildlife habitat structures that are likely to be used by wildlife, including wood duck houses, bat boxes, nesting platforms, snags, rootwads/stumps, birdhouses, and heron nesting areas.

4. Planting native vegetation within the buffer area, especially vegetation that would increase value for fish and wildlife, increase stream bank or slope stability, improve water quality, or provide aesthetic/recreational value; or
5. Creation of a surface channel where a stream was previously underground, in a culvert or pipe. Surface channels which area “daylighted” must be located within a buffer area and must be designed with energy dissipating functions or channel roughness features such as meanders and rootwads to reduce future bank failures or nearby flooding;
6. Removal or modification of existing stream culverts (such as road crossings) to improve fish passage, stream habitat, and flow capacities; or
7. Upgrading of retention/detention facilities or other stormwater management facilities beyond required levels.

#### **19.70.335 Fish and wildlife habitat – Specific Standards for Other FWHCAs**

**A. Endangered, Threatened, and Sensitive Species.** Fish and wildlife habitat conservation areas or buffers with which species that are State or Federally listed as endangered, threatened, or sensitive species, and anadromous fish species are subject to the following:

1. No development is allowed within a fish and wildlife habitat conservation area or buffer with which State or Federally endangered, threatened, or sensitive species have a primary association, except that which is provided for by a management plan established by the Washington Department of Fish and Wildlife or applicable State or Federal agency.
2. Whenever activities are proposed adjacent to a fish and wildlife habitat conservation area with which State or Federally endangered, threatened, or sensitive species have a primary association, such area must be protected through the application of protection measures in accordance with a critical area report prepared by a qualified professional and approved by the City. Approval for alteration of the fish and wildlife habitat conservation area or its buffer may not occur prior to consultation with the Washington Department of Fish and Wildlife for animal species, the Washington State Department of Natural Resources for plant species, and other appropriate Federal or State agencies.

**B. Other Priority Habitats and Species.** Fish and wildlife habitat conservation areas or buffers with which species that are not State or Federally listed as endangered, threatened, or sensitive species, and are not anadromous fish species are subject to the following:

1. Development activities and uses that result in unavoidable impacts may be permitted in priority species habitat areas and associated buffers in accordance with an approved critical area report with habitat assessment/management plan, and only if the proposed activity is the only reasonable alternative that will accomplish the applicant’s objectives. Full compensation for the loss of acreage and functions of habitat and buffer areas must be provided in compliance with the mitigation performance standards and requirements of these regulations.

## C. City-Designated Habitats and Species of Local Importance

### 1. Anacortes Community Forest Lands:

**Purpose.** The Anacortes Community Forest Lands include three lakes and their watersheds, numerous wetlands, rock bluffs, old growth forests, grassy knolls, windswept hilltops, sheltered caves, and a variety of other habitats and microclimates that provide a unique and irreplaceable habitat for both imperiled and commonplace species. This land has been dedicated by the City for the preservation of forest lands and species, as described in the Conservation Easement documents, the ACFL Comprehensive Plan, and in AMC Title 12.

- a. Recreation and Recreation-Related Facilities. Construction of public recreation-related facilities such as trails, benches, interpretive displays, and viewing platforms, may be allowed in fish and wildlife habitat conservation areas or buffers
- b. Proposed alterations must be consistent with the adopted Anacortes Community Forest Lands Comprehensive Plan, as amended.
- c. Noxious and Invasive Plants. The Skagit County noxious weed ordinance and the ACFL invasive plant control program must be carefully considered in any adjacent development decision. Nonnative plants known to be invasive into the ACFL must be prohibited in landscaping plans of adjacent developments. Where such developments have CC&Rs, reference to this requirement must be included therein.
- d. Right of Way Vacations. In the case of street or alley vacations contiguous with an ACFL boundary, the half of the area vacated which is adjacent to the ACFL must be incorporated into the ACFL and subject to all ACFL related requirements.
- e. Private Access to ACFL. No new accesses will be established to the ACFL without prior request for such access to the parks and recreation department and the forest advisory board and approval by the city council.
- f. Burning. No burn piles or outdoor fires must ever be left unattended while ignited and in the event sparks or flames come within three hundred feet of the ACFL, the fire must immediately be brought under control or extinguished.
- g. Boundary Identification. City staff will work closely with property owners and developers to ensure that survey lines adjacent to the ACFL boundary are clearly and correctly marked before any timber and/or vegetation is removed from adjacent property. The forest manager will be involved in the final inspection of boundary lines.
- h. ACFL Buffers. City staff will work closely with builders to secure thirty-foot ACFL buffers using all available incentives.

### 2. March Point Heronry:

2.

Commented [CT16]: Add Purpose Statement:

*Purpose. The Anacortes Community Forest Lands include three lakes and their watersheds, numerous wetlands, rock bluffs, old growth forests, grassy knolls, windswept hilltops, sheltered caves, and a variety of other habitats and microclimates that provide a unique and irreplaceable habitat for both imperiled and commonplace species. This land has been dedicated by the City for the preservation of forest lands and species, as described in the Conservation Easement documents, the ACFL Comprehensive Plan, and in the newly created Anacortes Municipal Code Title 12.*

Formatted: Font: Bold

Formatted: Indent: Left: 0.44", No bullets or numbering

Commented [CT17]: Change formatting to add Purpose Statement:

*Purpose. Because Skagit County is home to the greatest concentration of nesting Great Blue Heron in the Salish Sea, March Point being the largest, the City has identified the March Point Heronry as a habitat of local importance.*

Formatted: Indent: Left: 0.69", No bullets or numbering

**a. Purpose.** Because Skagit County is home to the greatest concentration of nesting Great Blue Heron in the Salish Sea, March Point being the largest, the City has identified the March Point Heronry as a habitat of local importance.

**b.a.** Proposed development activities within 1,000 feet, or that is likely to impact the colony, must provide a critical areas assessment report and habitat management plan that follows at a minimum the guidelines provided by WDFW's Management Recommendations for Washington's Priority Species (March 2012).

[https://wdfw.wa.gov/publications/00026/abbreviated\\_great\\_blue\\_heron.pdf](https://wdfw.wa.gov/publications/00026/abbreviated_great_blue_heron.pdf).

**b.b.** Buffers will be implemented as described in the buffer section below.

**b.c.** Colony protection is required for minimum 10-years after abandonment.

**D. Required Buffer for Non-Stream FWHCA's:**

1. **Marine FWHCA's Buffers.** Buffer for all designated fish and wildlife habitats or species within marine shorelines must be regulated by [AMC 19.72 Shoreline Regulations and the Shoreline Master Program](#), ~~incorporated Critical Area regulations.~~
2. **All Other Non-Stream FWHCA Buffers.** Buffers from fish and wildlife habitat conservation areas must be established to protect the functions and values of the critical area from the impacts of proposed adjacent activities.
  - a. Buffer widths for fish and wildlife habitat areas must be based on consideration of the following factors: species-specific recommendations of the Washington State Department of Fish and Wildlife; recommendations contained in a habitat management plan submitted by a qualified professional; and the nature and intensity of land uses and activities occurring on the land adjacent to the site. Buffers must:
    - i. Consist of an undisturbed area of native vegetation, or areas identified for restoration, sufficient to protect the integrity, functions, and values of the affected habitat;
    - ii. Reflect the sensitivity of the habitat and the type and intensity of human activity proposed to be conducted nearby;
    - iii. Be consistent with the applicable species-specific management recommendations issued by the Washington Department of Fish and Wildlife.
  - b. Nesting bald eagles and bald eagle habitat must be protected consistent with the U.S. Fish and Wildlife Service (USFWS) National bald eagle management guidelines, or the state or federal regulations in place at the time of application. Whenever activities are proposed adjacent to a confirmed nest territory or communal roost, a bald eagle habitat management plan must be developed by a qualified professional. Activities are adjacent to managed bald eagle sites when they are within 660 feet of a nest or within one-half

Formatted: Font: Bold

Formatted: Indent: Left: 0.38", No bullets or numbering

mile (2,640 feet) of a shoreline foraging area. Approval of the activity must not occur prior to consultation with the state or federal agency with authority on bald eagle pairs and their nest.

- c. Great Blue Heron nesting and breeding areas: Development near a verified heron breeding habitat including nesting colony areas, former nesting colonies, pre-nesting staging areas, and breeding season foraging habitat require:

- i. A year-round urban buffer of 197 feet,
- ii. For unusually loud activities that occur during breeding season (February – September) a seasonal buffer of 656 feet, and a Blasting buffer of ~~3,280~~ 1,320 feet.

- iii. For properties without an existing and approved management plan; A management plan developed by a qualified professional to follow, at a minimum, WDFW's Management Recommendations for Washington's Priority Species (March 2012) and that identifies the nesting and breeding site as well as pre-nesting staging area, and breeding season foraging habitat

- ~~iii-iv.~~ For the March's Point Colony, given the observed and documented sensitivity of this mega-colony to human intrusion and the fact that the colony is in a rare, isolated, but tight location, a year-round buffer of 984 feet.

#### 19.70.340 Fish and wildlife habitat – Buffer Width Averaging for All FWHCA's.

- A. Approval Criteria. The ~~Decision-maker~~ Decision-maker may allow the averaging of FWHCA buffer widths when the critical areas report demonstrates the following:
1. In-stream or buffer habitat functions, will be increased or maintained where native buffer vegetation is generally intact, or increased where existing buffer vegetation is inadequate to protect functions and values; and
  2. The buffer averaging does not reduce the functions or values of the stream or FWHCA buffer; and
  3. The total area contained in the buffer area after averaging on the development proposal site is no less than that which would be contained within the standard buffer, and all increases in buffer dimension for averaging must be parallel to the FWHCA buffer; and
  4. The stream or FWHCA buffer contains variations in sensitivity due to existing physical characteristics or the character of the buffer varies in slope, soils, or vegetation; and
  5. The buffer width is not reduced in any location to less than 50 percent of the standard width or 35 feet, whichever is greater, on a case-by-case basis as a result of a habitat assessment pursuant to AMC 19.70.380 (B)(4); and

Commented [CT18]: Change to read:

*Great Blue Heron nesting and breeding areas: Development near a verified heron breeding habitat including nesting colony areas, and former nesting colonies:*

- i. A year-round urban buffer of 197 feet,*
- ii. For unusually loud activities that occur during breeding season (February – September) a seasonal buffer of 656 feet, and a Blasting/Extreme noise buffer of 1,320 feet.*
- iii. For properties without an existing and approved management plan; a management plan developed by a qualified professional to follow, at a minimum, WDFW's Management Recommendations for Washington's Priority Species (March 2012) and that identifies the nesting and breeding site as well as pre-nesting staging areas, and breeding season foraging habitat.*
- iv. For the March's Point Colony, given the observed and documented sensitivity of this mega-colony to human intrusion and the fact that the colony is in a rare, isolated but tight location, a year-round buffer of 984 feet.*

6. The buffer has not been reduced in accordance with this section. Buffer averaging is not allowed if the buffer has been reduced; and
7. There were no feasible alternatives to the site design without buffer averaging; and
8. Buffer enhancement will be provided.
9. The buffer width reduction will not be located within another critical area or associated buffer; and
10. Only those portions of the FWHCA buffer within the project area or subject parcel may be considered in the total buffer area for buffer averaging.

**19.70.345 Fish and wildlife habitat – Stormwater Management Facilities.**

Establishment of low-impact stormwater management facilities, such as stormwater dispersion outfalls and bioswales, may be allowed within fish and wildlife habitat conservation area buffers consistent with the adopted stormwater manual; provided, that:

- A. No other location is feasible; and
- B. There will be “no net loss” of functions and values of the fish and wildlife habitat conservation area; and
- C. The critical area lies in the natural routing of the runoff, and the discharge follows the natural routing; and
- D. Stormwater dispersion outfalls, bioswales, bioretention facilities, and other low-impact facilities consistent with the adopted stormwater manual may be allowed within the outer 25% of the buffer when determined by a qualified professional that the location of the facilities will enhance the buffer area and protect the stream; and
- E. Such facilities are designed consistent with the requirements of AMC 19.76.

**19.70.350 Fish and wildlife habitat – Critical area report additional requirements.**

- A. **Additional Report Contents for FWHCA's.** In addition to the minimum report contents required per AMC 19.70.125 FWHCA reports must also include;
  1. Documentation of any fieldwork performed on the site, including field data sheets for delineations, water typing and other habitat conservation area classification, baseline hydrologic data, site photos, etc.;
  2. A description of the methodologies used to conduct the delineations, classifications, or impact analyses, including reference;
  3. A discussion of the potential impacts to the critical area or buffer associated with the proposed development including an assessment of cumulative impacts.
- B. **Habitat Assessment /Management Plan.** A habitat assessment /management plan is an investigation of the project area to evaluate the potential presence or absence of designated

Formatted: Font: Bold

critical fish or wildlife species or habitat. A critical area report for a fish and wildlife habitat conservation area must contain an assessment of habitats including the following site- and proposal-related information at a minimum:

1. Detailed description of vegetation on and adjacent to the project area and its associated buffer;
2. Identification of any species of local importance, priority species, or endangered, threatened, sensitive, or candidate species that have a primary association with habitat on or adjacent to the project area, and assessment of potential project impacts to the use of the site by the species;
3. A discussion of any Federal, State, or local special management recommendations, including Washington Department of Fish and Wildlife habitat management recommendations, that have been developed for species or habitats located on or adjacent to the project area;
4. A detailed discussion of the direct and indirect potential impacts on habitat by the project, including potential impacts to water quality;
5. A discussion of measures, including avoidance, minimization, and mitigation, proposed to preserve existing habitats and restore any habitat that was degraded prior to the current proposed land use activity and to be conducted in accordance with AMC 19.70.135, Mitigation Requirements;
6. A discussion of ongoing management practices that will protect habitat after the project site has been developed, including proposed monitoring and maintenance programs.

**C. Additional Technical Information Requirements for Streams.** If no project impacts are anticipated and standard stream buffer widths are retained, a stream delineation report, general critical areas report or other reports, alone or in combination, may be submitted as consistent with the specific requirements of this section. In addition to the general critical area report requirements for fish and wildlife habitat conservation areas provided in subsections A through D of this section, technical information on streams must include the following information at a minimum:

1. A written assessment and accompanying maps of the stream and associated hydrologic features on and off site within 300 feet of the project area, including the following information at a minimum: Stream survey showing the field delineated ordinary high water mark(s);
  - a. Standard stream buffer boundary as determined by AMC 19.70.340;
  - b. Boundary for proposed stream buffers averaging, if applicable;
  - c. Vegetative, faunal, and hydrologic characteristics;
  - d. Soil and substrate conditions; and

Formatted: Font: Bold

- e. Topographic elevations, at two-foot contours;
- 2. A detailed description and functional assessment of the stream channel and stream buffer under existing conditions pertaining to the protection of stream functions, fish habitat and, in particular, potential anadromous fisheries;
- 3. A habitat and native vegetation conservation strategy that addresses methods to protect and enhance on-site habitat and stream functions;
- 4. Proposed buffer enhancement, if needed, including a written assessment and accompanying maps and planting plans for buffer areas to be enhanced, including the following information at a minimum:
  - a. A description of existing buffer conditions;
  - b. A description of proposed buffer conditions and how proposed conditions will increase buffer functions in terms of stream and fish habitat protection;
  - c. Performance standards for measuring enhancement success through a monitoring period of at least five years; and
  - d. Provisions for monitoring and submission of monitoring reports documenting buffer conditions, as compared to performance standards, for enhancement success;
  - e. A discussion of ongoing management practices that will protect stream functions and habitat value through maintenance of vegetation density within the stream buffer.

**D. Additional Technical Information for Heron Habitat.**

- 1. The Report must identify the Heron Management Area (HMA). A HMA consist of the nesting colony, year-round and seasonal buffer, foraging habitat, and when present, a pre-nesting congregation area.
- 2. All survey activity such as nest tree identification and flagging **should occur in the non-breeding season (mid-September to mid-February)**, and preferably right after breeding season ends.
- 3. Identify the nesting colony's boundary. To do this flag all nest trees at the colony's outer perimeter. Mark each of these trees on a map. If a nest tree's canopy overlaps the canopy of an adjacent tree, flag the adjacent tree and consider this to be a nest tree. The outermost nest trees will be used to map the nesting colony boundary.
- 4. Map outer perimeter of the 197 foot year-round buffer. Using the buffer radius, draw a circle around each peripheral nest tree.
- 5. Map seasonal buffer if any unusually loud activities will occur during breeding season (February – September). Measure the seasonal buffer starting at the outer edge of the year-round buffer.

6. Locate potential foraging habitat by mapping all waterbodies within a 1.9 mile radius of the colony. The perimeter and shallow portions are especially important for foraging.

**E. Additional FWHCA information.** When appropriate due to the type of habitat or species present, or the project area conditions, the ~~Decision Maker~~[Decision-maker](#) may also require the critical area report to include:

1. A request for consultation with the Washington State Department of Fish and Wildlife (DFW), Washington Department of Ecology (Ecology), local Native American ~~Indian~~ tribes or other appropriate agency;
2. Copies of the Joint Aquatic Resource Permit Application (JARPA) and related approvals, such as a Hydraulic Project Approval (HPA) from the WDFW, when applicable to the project; and
3. Detailed surface and subsurface hydrologic features both on and adjacent to the site.

**19.70.355 Fish and wildlife habitat – Mitigation performance standards and requirements.**

- A. Compensatory mitigation for FWHCA's must follow the plan requirements described under AMC 19.70.135.

---

## **PART4: GEOLOGICALLY HAZARDOUS AREAS**

---

**19.70.410 Geologically Hazardous Areas– Description and Purpose.**

- A. Geologically hazardous areas include areas susceptible to the effects of erosion, landslides, earthquake, or other geologic events. They pose a threat to health and safety of citizens when incompatible development is sited in areas of significant hazard.
- B. The primary purpose of these regulations is to avoid and minimize potential impacts to life and property from geologic hazards, conserve soil resources, and minimize structural damage relating to these hazards. The purpose is accomplished through appropriate levels of study and analysis, application of sound engineering principles, and regulation or limitation of land uses, including maintenance of existing vegetation, regulation of clearing and grading activities, and control of stormwater.

**19.70.415 Geologically Hazardous Areas - Designation.**

- A. Areas susceptible to one or more of the following types of hazards are designated as a geologically hazardous area:
  1. **Erosion Hazard Areas.** Erosion hazard areas include areas likely to become unstable, such as bluffs, steep slopes, and areas with unconsolidated soils. The following are considered known or suspected erosion hazards:
    - a. Areas located within the following soil map units: Nos. 46 and 47 Dystric Xerochrepts; No. 90 Lithic Haploxerolls-Rock outcrop complex (LH), or mapped severe erosion

hazard, as identified in the U.S. Department of Agriculture Natural Resources Conservation Service Soil Survey of Skagit County Area, WA (1989).

- b. Coastal, erosion-prone areas such as beaches or marine bluffs.
- c. Areas susceptible to rapid stream incision and stream bank erosion.

2. **Landslide Hazard Areas.** Landslide hazard areas are those areas subject to landslide activity based on a combination of geologic, topographic, and hydrologic factors. They include areas susceptible because of any combination of bedrock, soil, slope (gradient), slope aspect, structure, hydrology, or other factors. The following are known or suspected landslide hazards:

- a. Areas designated in the Washington State Department of Ecology Coastal Zone Atlas, Washington, Volume Two Skagit County (1978) as U (Unstable), UB, (Unstable Bluff), URS (Unstable Recent Slide), or UOS (Unstable Old Slide).
- b. Areas of previous failure such as earth slumps, earthflows, mudflows, lahars, debris flows, rock slides, landslides or other failures as observed in the field or as indicated on maps or in technical reports published by the U.S. Geological Survey, the Geology and Earth Resources Division of the Washington Department of Natural Resources, or other documents authorized by government agencies.
- c. Slopes having gradients of 15% or greater:
  - i. That intersect geologic contacts with permeable sediments overlying low-permeability sediment or bedrock and springs or groundwater seepage are present; or
  - ii. That are parallel or subparallel to planes of weakness (such as bedding planes, joint systems, and fault planes) in subsurface materials.
- d. Areas that have shown movement during the Holocene epoch (from ten thousand years ago to the present) or that are underlain or covered by mass wastage debris of that epoch.
- e. Slopes having gradients steeper than 80% subject to rock fall during seismic shaking.
- f. Potentially unstable areas resulting from rapid stream incision, stream bank erosion, and undercutting by wave action.
- g. Slopes with a gradient of 40% or more with a vertical relief of 10 feet or more, including marine bluffs, except areas composed of consolidated rock. A slope is delineated by establishing its toe and top and is measured by averaging the inclination over at least 10 feet of vertical relief.

3. **Seismic Hazard Areas.** Seismic hazard areas are lands that, due to a combination of soil and groundwater conditions, are subject to risk of damage as a result of earthquake

induced ground shaking, slope failure, settlement or subsidence, soil liquefaction, or surface faulting. The following are known or suspected seismic hazards:

- a. Areas having “high” and “moderate to high” risk of liquefaction as mapped on the Liquefaction Susceptibility and Site Class Maps of Western Washington State by County published by the Washington State Department of Natural Resources. These are typically underlain by cohesionless soils of low density typically and must [have a](#) low groundwater table.
  - b. Areas located within ¼ mile of an active fault as indicated on investigative maps or described in studies by the United States Geologic Survey, Geology and Earth Resources Division of the Washington Department of Natural Resources, or other documents authorized by government agencies, or identified during site inspection.
  - c. Those known or suspected landslide hazards referenced in Subsection (2) of this Section.
4. **Mine Hazard Areas.** Mine hazard areas are those areas underlain by or affected by mine workings such as adits, gangways, tunnels, drifts, or airshafts, and those areas of probable sink holes, gas releases, or subsidence due to mine workings. Factors that should be considered include: proximity to development, depth from ground surface to mine working, and geologic material.
5. **Volcanic Hazard Areas.** Volcanic hazard areas are areas subject to pyroclastic flows, lava flows, debris avalanche, and inundation by debris flows, lahars, mudflows, or related flooding resulting from volcanic activity. Though there are no significant risks identified for the City and immediate surrounding area, other than airborne particulate impacts from an eruptions
6. **Tsunami hazard areas.** Tsunami hazard areas include coastal areas and lake shoreline areas susceptible to flooding, inundation, debris impact, and/or mass wasting as the result of coastal wave action generated by seismic events or other geologic events. Suspected tsunami hazard areas are indicated on the Tsunami Hazard Map of the Anacortes-Whidbey Island Area, Washington: Modeled Tsunami Inundation from a Cascadia Subduction Zone Earthquake.
7. **Other Hazard Areas.** Geologically hazardous areas may also include areas determined by the ~~Decision-maker~~[Director](#) to be susceptible to other geological events including mass wasting, debris flows, rock falls, and differential settlement.
- B. All areas within the city meeting one or more of these criteria, regardless of any formal identification, are hereby designated critical areas and are subject to the provisions of this chapter.

#### **19.70.420 Geologically Hazardous Areas – Mapping.**

- A. The approximate location and extent of geologically hazardous areas are shown on the City of Anacortes geologically hazardous data layers maintained in the City of Anacortes geographic information system (GIS). In addition, the following maps and resources providing information on the location and extent of geologically hazardous areas are hereby adopted by reference as amended:
1. Skagit County, Skagit County Potential Landslide and Erosion Areas, 2016;
  2. Washington Department of Ecology Coastal Zone Atlas (for marine bluffs);
  3. U.S. Geological Survey geologic maps, landslide hazard maps, and seismic hazard maps;
  4. Washington State Department of Natural Resources seismic hazard maps for Western Washington, including, but not limited to, the Liquefaction Susceptibility and Site Class Maps of Western Washington State by County;
  5. Washington State Department of Natural Resources slope stability maps;
  6. Soils maps produced by the U.S. Department of Agriculture, National Resources Conservation Service;
  7. National Oceanic and Atmospheric Administration tsunami hazard maps;
  8. Washington Department of Natural Resources Tsunami Hazard Map, or as updated, of the Anacortes-Whidbey Island Area, Washington: Modeled Tsunami Inundation from a Cascadia Subduction Zone Earthquake.
- B. **Reference Only.** The maps and resources cited above are to be used as a guide for the City of Anacortes Planning, Community & Economic Development Department, project applicants, and/or property owners and may be continuously updated as new critical areas are identified. They are a reference and do not provide a final critical area designation.

#### **19.70.425 Geologically Hazardous Areas – General Development Standards.**

- A. All development activities and uses are prohibited in geologically hazardous areas and their buffers, except as provided for in this chapter, and only when it is demonstrated that the activity will not create undue risk to life, health, and safety.
- B. **Exemptions and Allowed Activities.** Exemptions are listed in the provisions established in AMC AMC 19.70.035 Exempt Activities.
- C. **Approvals.** Alterations of geologically hazardous areas or associated buffers may only occur pursuant to this chapter, and as determined by a qualified professional with concurrence by a 3<sup>rd</sup> party review, for activities that:
1. Will not increase the threat of the geological hazard to adjacent properties beyond pre-development conditions;

2. Will not adversely impact other critical areas;
  3. Are designed so that the hazard to the project is eliminated or mitigated to a level equal to or less than pre-development conditions; and
  4. Are determined to be safe as designed and under anticipated conditions by a qualified professional, licensed in the state of Washington.
- D. **Mitigation.** Proposed mitigation techniques are considered to provide long-term hazard reduction only if they do not require regular maintenance or other actions to maintain their function. Mitigation may be required to avoid any increase in risk above the preexisting conditions, including following abandonment of the activity.
- E. **Critical Facilities Prohibited.** Critical facilities may not be sited within geologically hazardous areas unless there is no other practical alternative.
- F. **International Building Code.** All development must conform to the provisions of the currently adopted International Building Code as amended by the City of Anacortes, including submittal of a critical areas report.

#### 19.70.430 Geologically Hazardous Areas – Specific Development Standards

- A. **Erosion or Landslide Hazard Areas.** Except as otherwise provided in this Chapter, only those activities approved and permitted consistent with an approved critical area report in accordance with this Chapter are allowed in erosion or landslide hazard areas. Activities must meet the standards of AMC 19.70.430, General development standards, in addition to the specific requirements contained in this subsection.
1. **Standard Buffer.** A standard buffer of 50 feet is required from the closest edge of a landslide hazard area. The buffer must be maintained as undisturbed native vegetation, except when alteration of vegetation is approved by the ~~Decision-maker~~Decision-maker as part of the project.
  2. **Buffer reduction.** The ~~Decision-Maker~~Decision-maker may reduce the standard buffer by a ~~minimum-maximum~~ of 25% when the critical area report demonstrates that all of the following criteria are met:
    - a. No reasonable alternative to the buffer reduction exists;
    - b. Modified or reduced buffers, through design and engineering solutions, will provide protection to the proposed development and adjacent properties equal to that of the standard buffer;
    - c. The development will not increase surface water discharge or sedimentation to adjacent properties beyond pre-development conditions;
    - d. The development will not decrease slope stability on adjacent properties;
    - e. The proposed reduction will not adversely impact other critical areas;

- f. The critical areas report makes recommendations regarding planting of vegetation or other measures to minimize impacts and resist erosion.
  - g. When a buffer reduction is requested the ~~Decision-maker~~Decision-maker may require, at the applicant's expense, a third-party review of a critical area report by a Qualified Professional under contract with or employed by the City.
3. **Increased buffer.** The standard buffer may be increased by the ~~Decision-maker~~Decision-maker based on a critical areas report prepared by a qualified professional that indicates a greater buffer is necessary to protect the proposed development and/or adjacent properties.
4. **Alterations.**
- a. Alterations of a marine bluff or its buffer are prohibited except that minor development to provide public access (e.g. public trails, stairs or view points) may be permitted as regulated in the Shoreline Master Program, provided that impacts are mitigated and the development can be shown to be safe.
  - b. Alterations of an erosion or landslide hazard area and/or buffers may only occur for activities for which a critical areas report that contains a hazards analysis is submitted which determines that:
    - i. The activity will not increase surface water discharge or sedimentation to adjacent properties beyond predevelopment conditions;
    - ii. The activity will not decrease slope stability on adjacent properties;
    - iii. Such alteration will not adversely impact other critical areas or pose a potential threat risk to life, health, and safety.
  - c. Alterations must be designed to meet the following basic requirements:
    - i. The proposed alteration must not decrease the slope stability. The factor of safety against landslide occurrences for residential and commercial developments must be 1.5 for static conditions and 1.2 for dynamic conditions, unless approved by the ~~Decision-maker~~Decision-maker. Analysis of dynamic conditions must be based on a minimum horizontal acceleration as established by the current version of the International Building Code.
    - ii. Structures and improvements must be clustered to avoid geologically hazardous areas and other critical areas,
    - iii. Structures and improvements must minimize alterations to the natural contour of the slope, and foundations must be tiered where possible to conform to existing topography,
    - iv. Structures and improvements must be located to preserve the most critical portion of the site and its natural landforms and vegetation,

- v. The proposed development must not result in greater risk or a need for increased buffers on neighboring properties;
  - vi. Development must be designed to minimize impervious lot coverage;
  - vii. The ~~Decision-maker~~[Decision-maker](#) may accept an alternative design that deviates from one or more of these standards if a report by a qualified professional demonstrates that greater long-term slope stability can be achieved while meeting all other provisions of this title. The requirement for long-term slope stability must exclude designs that require regular and periodic maintenance to maintain their level of function.
- d. **Additional Requirements for Alteration of Landslide hazard areas and buffers.** Prior to permit issuance, the property owner must sign and record a notice on title, at the owner's sole expense, a covenant in a form acceptable to the City, which:
- i. Acknowledges and accepts the risks of development in the landslide hazard area;
  - ii. Waives any rights to claims against the City;
  - iii. Indemnifies and holds harmless the City against claims, losses, and damages;
  - iv. Informs subsequent owners of the property of the risks and the covenant; and
5. **Vegetation Retention and Maintenance.** Removal of vegetation from a landslide hazard area or related buffer is prohibited, except when allowed as follows:
- a. As part of an approved alteration, that follows the criteria and process outlined in AMC 19.70.440(A)(4).
  - b. Normal nondestructive pruning and trimming of vegetation for maintenance purposes or thinning of limbs of individual trees to provide a view corridor when a plan prepared by an ISA-certified arborist is provided and approved by the ~~Decision-maker~~[Decision-maker](#) and there are no other critical areas present.
  - c. All activity proposed on Marine Bluffs must be regulated and reviewed under the SMP and required shoreline permitting.
6. **Seasonal Restriction.** Clearing within an erosion or landslide hazard area or buffer may be allowed only from May 1st to October 1st of each year provided that the ~~Decision-maker~~[Decision-maker](#) may extend or shorten the dry season on a case-by-case basis depending on actual weather conditions and other factors deemed relevant.
7. **Utility Lines and Pipes.** Utility lines and pipes may be permitted in landslide hazard areas and buffers only when the applicant demonstrates that no other practical alternative is available. The line or pipe must be located aboveground and properly anchored and/or designed with the intent to function in the event of an underlying slide.
8. **Stormwater management.** Prior to any development activity, a plan for the collection, transport, treatment, and discharge of stormwater in accordance with the requirements of

AMC Chapter 19.76, or as amended, and in accordance with the adopted Stormwater Management Manual for Western Washington, must be submitted meeting the following requirements:

- a. All infiltration systems, such as stormwater detention and retention facilities, and curtain drains utilizing buried pipe or French drains, are prohibited in landslide hazard areas and their buffers unless the critical areas report determines such facilities or systems will not adversely affect slope stability.
- b. Stormwater may not be directed across the face of a landslide hazard or related buffer (including marine bluffs or ravines) except as follows:
  - i. Stormwater may be discharged at flow durations matching predeveloped conditions, with adequate energy dissipation, into existing channels that previously conveyed stormwater runoff in the predeveloped state;
  - ii. Stormwater may be dispersed upslope of the landslide hazard area onto a low-gradient undisturbed buffer demonstrated to be adequate to infiltrate all surface and stormwater runoff, if the critical areas report determines such facilities or systems will not adversely affect slope stability;
  - iii. If demonstrated that no other practical alternative is available, stormwater may be discharged from the hazard area into adjacent waters, provided it is collected above the hazard and directed to the water by a tight line drain (constructed of high-density polyethylene pipe with fuse-welded joints, or similar product that is technically equal or superior) and provided with an energy dissipating device at the point of discharge.

9. **Prohibited development.** On-site sewage disposal systems, including drain fields, are prohibited within erosion and landslide hazard areas and related buffers.

10. **Subdivisions.**

- a. The division of land in landslide hazard areas and associated buffers is subject to the following:

i. Land that is located wholly within a landslide hazard area or its buffer may not be subdivided. Land that is located partially within a landslide hazard area or its buffer may be divided provided that each resulting lot has sufficient buildable area outside of, and will not affect, the landslide hazard or its buffer;

ii. Access roads and utilities may be permitted within the landslide hazard area and associated buffers if the ~~Decision-maker~~[Decision-maker](#) determines that no other feasible alternative exists, and if the critical areas report determines such development will not adversely affect slope stability

b. Division of land within erosion hazard areas must comply with the following additional requirements:

i. Except as otherwise provided in this section, existing vegetation must be retained on all lots until building permits are approved for development on individual lots;

ii. If any vegetation on the lots is damaged or removed during construction of the subdivision infrastructure, the applicant must implement a revegetation plan in those areas that have been impacted prior to final inspection of the site development permit or the issuance of any building permit for the subject property;

iii. Clearing of vegetation on individual lots may be allowed prior to building permit approval if the ~~Decision-maker~~[Decision-maker](#) determines that:

1. Such clearing is a necessary part of a large-scale grading plan,
2. It is not feasible to perform such grading on an individual lot basis, and
3. Stormwater output from the graded area will meet established water quality standards.

**B. Seismic Hazard Areas.**

1. Activities proposed to be located in seismic hazard areas must meet the standards of AMC 19.70.430(B) and (E).

**C. Mine Hazard Areas.**

1. Activities proposed to be located in mine hazard area must meet the standards of AMC 19.70.430 General development standards, and the specific following requirements:
  - a. **Alterations.** Alterations of a mine hazard area and/or buffer are allowed, as follows:

- i. All alterations are permitted within a mine hazard area with a low potential for subsidence,
  - ii. Within a mine hazard area with a moderate potential for subsidence and at coal mine by-product stockpiles, all alterations are permitted subject to a mitigation plan to minimize risk of structural damage using appropriate criteria to evaluate the proposed use, as recommended in the hazard analysis, and
  - iii. Within a mine hazard area with a severe potential for subsidence only those activities allowed in AMC 19.70.035 **Exempt activities** of this chapter will be allowed.
- b. **Subdivisions.** The division of land in mine hazard areas and associated buffers is subject to the following:
- i. Land that is located within two hundred feet of a mine hazard area with a severe potential for subsidence may not be subdivided. Land that is located partially within a mine hazard area may be divided provided that each resulting lot has sufficient buildable area that is two hundred feet away from the mine hazard area with a severe potential for subsidence. Land that is located within a mine hazard area with a low or moderate potential for subsidence may be subdivided;
  - ii. Access roads and utilities may be permitted within two hundred feet of a mine hazard area with a moderate or severe potential for subsidence if the city determines that no other feasible alternative exists.
- c. **Reclamation Activities.** Reclamation activities must conform to the provisions in Chapter 332-18 WAC Excavations For all reclamation activities, including grading, filling, and stockpile removal, as-built drawings must be submitted to the city in a format specified by the ~~Decision-maker~~[Decision-maker](#).

#### D. Tsunami Hazard Areas.

1. Non-residential activities on sites containing areas susceptible to inundation due to tsunami hazards must provide an evacuation and emergency management plan
2. The construction of structures designated Risk Categories III and IV as specified under currently adopted IBC are prohibited within a tsunami hazard area, except that:
  - a. A vertical evacuation tsunami refuge may be permitted to be located in a tsunami hazard zone provided it is constructed in accordance with FEMA P646;

- b. Community critical facilities may be permitted to be located within a tsunami hazard zone when such a location is necessary to fulfill their function, provided suitable structure and emergency evacuation measures have been incorporated.

#### **19.70.435 Geologically Hazardous Areas - Critical Area Report Additional Requirements**

- A. **Additional Report Contents for Geologically Hazardous Areas.** In addition to the minimum report contents required per AMC 19.70.125 reports must also include;
- B. **Third Party Review Required.** Critical areas reports on geologically hazardous areas are subject to third party review at the owner's sole expense as provided in AMC 19.70.125 (B) and in any of the following circumstances:
  - 1. A buffer reduction or alteration of a landslide hazard area is proposed.
- C. **Minimum Report Contents for Geologically Hazardous Areas.** The written critical area report(s) must contain the following information, at minimum:
  - 1. The report must generally follow the Washington State Department of Licensing Guidelines for Preparing Engineering Geology Reports in Washington (2006) and at a minimum report contents required per AMC 19.70.125;
  - 2. A detailed overview of the field investigations, exploration locations, site photos, published data and references; data and conclusions from past assessments of the site; investigations or studies that support the identification of geologically hazardous areas;
  - 3. A description of the methodologies used to conduct the geologically hazardous areas evaluations, classification, hazards assessments, and/or analyses of the proposal impacts, including references.
- 4. **Assessment of Geological Characteristics.** The assessment must include the following:
  - a. Classification of the type of geologic hazard(s) present in accordance with AMC 19.70.410.
  - b. An assessment of the geologic characteristics of the soils, sediments, and/or rock of the project area and potentially affected adjacent properties, and a review of the site history regarding landslides, erosion, and prior grading. Soils analysis must be accomplished in accordance with accepted classification systems in use in the region.
  - c. A description of load intensity, surface and groundwater conditions, public and private sewage disposal systems, fills, excavations, and all structural development; and
  - d. A description of the extent and type of vegetative cover;
  - e. An analysis of proposed surface and subsurface drainage, and the vulnerability of the site to erosion;

5. **Analysis of Proposal.** The report must include a detailed description of the project, its relationship to the geologic hazard(s), and its potential impact upon the hazard area, the project, the subject property, and affected adjacent properties.
6. **Minimum Buffer and Building Setback.** The report must make a recommendation for the minimum no-disturbance buffer and minimum building setback from any geologic hazard based upon the geotechnical analysis.
7. **Additional Technical Information Requirements for Specific Hazards:**
  - a. **Erosion and Landslide Hazard Areas.** The technical information required in a critical area report for a project within an erosion or landslide hazard area must also include the following:
    - i. An estimate of the present stability of the subject property, the stability of the subject property during construction, the stability of the subject property after all development activities are completed, and a discussion of the relative risks and slide potential relating to adjacent properties during each stage of development, including the effect of construction and placement of structures, clearing, grading, and removal of vegetation will have on the slope over the estimated life of the structures. Quantitative analysis of static and seismic slope stability, modeling, and/or seismic displacement analysis may be required by the [Decision-maker](#).
    - ii. A trend analysis of prior rates of erosion, if available.
    - iii. Consideration of the run-out hazard of landslide debris and/or the impacts of landslide run-out on downslope properties;
    - iv. Recommendations for stormwater improvements, locations and methods of erosion control, vegetation management, and/or other means for maintaining long-term soil stability;
    - v. Parameters for design of site improvements including appropriate foundations and retaining structures. These should include allowable load and resistance capacities for bearing and lateral loads, installation considerations, and estimates of settlement performance;
    - vi. Earthwork recommendations including clearing and site preparation criteria, fill placement and compaction criteria, temporary and permanent slope inclinations and protection, and temporary excavation support, if necessary; and
    - vii. Recommendations for mitigation measures to be implemented in order to minimize the risk to the site and adjacent properties, including slope stabilization measures, if appropriate.

b. **Seismic Hazard Areas.** The technical information required in a critical area report for a project within a seismic hazard area must also include the following:

- i. A complete discussion of the potential impacts of seismic activity on the site (for example, liquefaction, lateral spreading, fault rupture);
- ii. An evaluation of the subsurface soil and groundwater profile, physical properties of the subsurface profiles, and the liquefaction potential of the site;
- iii. Recommendations for mitigation measures to be implemented in order to minimize the risk to the project, and adjacent properties if appropriate.

c. **Tsunami Hazard Areas.** The technical information required in a critical area report for a project within a tsunami hazard area must also include:

- i. A discussion of the potential impacts of the tsunami hazard on the site; and
- ii. Recommendations as to structure construction techniques including but not limited to the use of coastal high hazard performance standards.
- iii. For all development other than single lot, single family residences, an emergency management plan including plans for emergency building exits routes, site evacuation routes, emergency training, notification of local emergency management officials, and an emergency warning system.

d. **Marine Bluffs** A geotechnical engineering report will be required when development is proposed within 50 feet (in all directions) of ~~the to or to the~~ crest of a marine bluff, or a distance equal to the height of the slope up to a distance of 100 feet from the crest (measured from the top), whichever is greater.

- i. The report must be based on best available science, existing and proposed uses, risks of slope failure, and coastal erosion rates over the last 75 years, if applicable.
- ii. All proposed development on a marine bluff or in the required buffer must be prohibited, except: as may be allowed [in the shoreline-specific Critical Areas Regulations under Subsection A 3.5 of Appendix A of this per AMC 19.72 and DR-6.9.1 of the Shoreline Master Program](#), or minor development to provide public access (e.g., public trails, stairs or view points), provided that impacts are mitigated and the development can be shown to be safe.

D. **All Geologically Hazardous Areas.** The ~~Decision-Maker~~Director may require additional information deemed necessary to adequately review the proposal.

1. **Site and Construction Plans.** The critical area submittal for geologically hazardous areas must include a copy of the site plans for the proposal, drawn at an engineering scale, showing:
  - a. The type and extent of geological hazard areas, ~~and~~ any other critical areas, and recommended and required buffers on, adjacent to, off site within 200 feet of, or that are likely to impact or be affected by the proposal;
  - b. Proposed development, including the location of existing and proposed structures, fill, clearing limits, significant trees to be removed, vegetation to be removed, proposed material stock pile locations, and stormwater management facilities;
  - c. The topography, in two-foot contours, of the project area and all hazard areas addressed in the report;
  - d. Height of slope, slope gradient, and cross-section of the project area indicating the stratigraphy of the site;
  - e. The location of springs, seeps, or other surface expressions of ground-water on or off site within 200 feet of the project area or that have the potential to affect or be affected by the proposal;
  - f. The location and description of surface water on or off site within 200 feet of the project area or that has the potential to be affected by the proposal.

---

## **PART 5: CRITICAL AQUIFER RECHARGE AREAS**

---

### **19.70.510 Critical Aquifer Recharge Areas – Description and Purpose.**

- A. Critical aquifer recharge areas provide the public with clean, safe, and available drinking water and contribute base flows to protect aquatic resources. Once groundwater is contaminated or depleted, it is difficult, costly, and sometimes impossible to clean up or to recharge.
- B. The purpose of this section is to protect critical aquifer recharge areas from degradation or depletion resulting from new and redeveloping land use activities. Due to the potential vulnerability of groundwater underlying certain aquifer recharge areas to contamination and the importance of such groundwater as sources of public water supply, it is the intent of this section to safeguard groundwater resources by mitigating or precluding future discharges of contaminants from new development activities and redevelopment activities.

### **19.70.515 Critical aquifer recharge areas - Applicability and hazardous materials questionnaire.**

- A. **Applicability.** The provisions of this section apply to regulated facilities that are within or adjacent to those portions of the City of Anacortes designated as critical aquifer recharge

areas on the City of Anacortes Critical Areas Map. Regulated activities/facilities are defined as those commercial, industrial and home occupation uses that:

1. Process or handle hazardous materials in regulated quantities; and
2. Treat or store regulated quantities of hazardous materials.

**B. Hazardous materials questionnaire required.** Applications for development or redevelopment of regulated facilities within the boundaries of critical aquifer recharge areas must be accompanied by a completed hazardous materials questionnaire to determine the regulatory status of the applicant facility. The ~~Decision-maker~~[Decision-maker](#) must review the questionnaire to determine whether the facility is regulated under this chapter. If it is determined that the proposal includes a regulated facility that processes, handles, treats, and/or stores hazardous substances as defined by this chapter, the applicant must submit a critical areas report pursuant to this Chapter.

#### **19.70.520 Critical Aquifer recharge areas – Designation.**

**A.** Critical aquifer recharge areas include:

1. Areas served by groundwater which have been designated as a “Sole Source Aquifer Area” under the Federal Safe Drinking Water Act;
  - a. Areas within a “closed” or “low-flow” stream watershed designated by the Department of Ecology pursuant to RCW 90.22;
  - b. Areas designated as “Wellhead Protection Areas” pursuant to [WAC 246-290](#) and the groundwater contribution area pursuant to [WAC 246-291-125\(3\)\(d\)\(iii\)](#) or otherwise recognized by the ~~Decision-maker~~[Director](#) as needing wellhead protection. Wellhead protection areas include, for the purpose of this regulation, the identified recharge areas associated with:

- i. The 10-year groundwater time-of-travel for all Group A public water supply wells; or
  - i. The 5-year groundwater time-of-travel for all Group B public water supply wells with a wellhead protection plan filed with the Skagit County Health Department; or
  - ii. Plats serviced by five or more individual wells where the average lot size is equal to or less than two acres for which a wellhead protection plan has been completed and filed with the Skagit County Health Department; or
  - iii. The 1,000-foot radius for individual private drinking water supply wells, as identified by map criterion in section 10.70.530.
- B. All areas within the city meeting one or more of these criteria, regardless of any formal identification, are hereby designated critical areas and are subject to the provisions of this chapter.

#### **19.70.525 Critical Aquifer Recharge Areas – Mapping.**

- A. The approximate location and extent of critical aquifer recharge areas are shown on the City of Anacortes critical aquifer recharge area data layers maintained in the City of Anacortes geographic information system (GIS). In addition, the following maps and resources providing information on the location and extent of critical aquifer recharge areas are hereby adopted by reference as amended:
  - 1. Areas with soils that have moderate to rapid permeability (>2 inches per hour) as listed in Table 14 of the Soil Survey of Skagit County.
  - 2. Source for identifying drinking water supply wells identified by Agencies such as Washington Department of Ecology and Skagit County Health Department.
- B. **Reference Only.** The maps and resources cited above are to be used as a guide for the City of Anacortes Planning, Community & Economic Development Department, project applicants, and/or property owners and may be continuously updated as new critical areas are identified. They are a reference and do not provide a final critical area designation.

#### **19.70.530 Critical Aquifer Recharge Areas – General Development Standards**

- A. Regulated activities/facilities may be permitted in a critical aquifer recharge area only if the applicant can demonstrate that the proposed activity will not cause contaminants to enter the aquifer and that the proposed activity will not adversely affect the recharging of the aquifer.
- B. The proposed regulated activity must comply with the water source protection requirements and recommendations of the federal Environmental Protection Agency, State Department of Health, and the Skagit County Health Department.

- C. **Storage tank permits.** The City of Anacortes specifically regulates and authorizes permits for underground storage tanks pursuant to the International Fire Code and this chapter. The Washington Department of Ecology also regulates and authorizes permits for underground storage tanks (WAC 173-360). The Anacortes Fire Department regulates and authorizes permits for the removal of underground storage tanks.
- D. Owners and operators of facilities with existing underground storage tanks that are located within a critical aquifer recharge area must comply with all release detection requirements as specified in WAC 173-360.
- E. **Spreading or injection of reclaimed water.** Water reuse projects for reclaimed water must be in accordance with the adopted water or sewer comprehensive plans that have been approved by the Washington Department of Ecology and Skagit County Health Department.
1. Surface spreading must meet the groundwater recharge criteria given in RCW 90.46.080 and 90.46.010(10).
  2. Direct injection must be in accordance with the standards developed by authority of RCW 90.46.042.
- F. **Prohibited activities and land uses.** The following land uses and activities for new development or redevelopment are prohibited within or adjacent to critical aquifer recharge areas:
1. Landfill activities as defined in WAC 173-304 and WAC 173-351;
  2. All underground injection wells as defined in Chapter 173-218 WAC;
  3. Disposal of hazardous or dangerous wastes;
  4. Mining, including:
    - a. Metals and hard rock mining;
    - b. Sand and gravel mining are prohibited in critical aquifer recharge areas determined to be highly susceptible or vulnerable unless a stormwater quality management plan is approved and followed by the applicant;
  5. Wood Treatment Facilities. Wood treatment facilities that allow any portion of the treatment process to occur over permeable surfaces (both natural and manmade);
  6. Storage, processing, or disposal of radioactive substances;
  7. Dry cleaning establishments using the solvent perchlorethylene; and
  8. Other:
    - a. Activities that would significantly reduce the recharge to aquifers currently or potentially used as a potable water source;

- b. Activities that would significantly reduce the recharge to aquifers that are a source of significant baseflow to a regulated stream;
- c. Activities that are not connected to an available sanitary sewer system are prohibited from critical aquifer recharge areas associated with sole source aquifers.

**19.70.535 Critical Aquifer Recharge Areas – Specific Development Standards for Regulated Facilities**

- A. The following mitigation measures, as applicable, are required for development of regulated facilities within a critical aquifer recharge area:
  - 1. Floor drains must not be allowed to drain to the stormwater system and must be designed and installed to meet the Uniform Plumbing Code (UPC) Section 303.
  - 2. If any roof venting carries contaminants, then the portion of the roof draining this area must go through pretreatment pursuant to UPC Section 304(b).
  - 3. All nonresidential vehicle washing must be self-contained or be discharged to a sanitary sewer system, if approved by the sewer utility, and is subject to UPC Sections 708 and 711.
  - 4. Utilize Integrated Pest Management (IPM) practices for pest control and Best Management Practices (BMPs) for the use of fertilizers as described by the Skagit County Local Hazardous Waste Management Program.
  - 5. Facilities installing new underground tanks. All new underground storage facilities used or to be used for the underground storage of hazardous substances or hazardous wastes must meet the requirements of WAC 173-360 and be designed and constructed so as to:
    - a. Prevent releases due to corrosion or structural failure for the operational life of the tank;
    - b. Be protected against corrosion, constructed of non-corrosive material, steel clad with a non-corrosive material, or designed to include a secondary containment system to prevent the release or threatened release of any stored substance; and
    - c. Use material in the construction or lining of the tank which is compatible with the substance to be stored.
  - 6. Aboveground tanks. All new aboveground storage facilities/tanks containing hazardous substances within a critical aquifer recharge area must be constructed, installed, used and maintained to:
    - a. Prevent the release of a hazardous substance to the ground, or groundwater;
    - b. Include an impervious containment area enclosing or underlying the tank or part thereof;
    - c. Include a secondary containment system either built into the tank structure or a dike system built outside the tank. The secondary containment system or dike system must

have a capacity of at least 110 percent of the primary tank and conform to the requirements of UFC Chapter 7902.2.

7. Vehicle repair and servicing.
  - a. Commercial vehicle repair and servicing must be conducted over impermeable pads and within a covered structure capable of withstanding normally expected weather conditions. Chemicals used in the process of vehicle repair and servicing must be stored in a manner that protects them from weather and provides containment should leaks occur.
  - b. Dry wells are not allowed on sites used for vehicle repair and servicing. Dry wells existing on the site prior to facility establishment must be abandoned using techniques approved by the state Department of Ecology prior to commencement of the proposed activity.
8. Additional protective measures may be required if deemed necessary by the City of Anacortes.
9. State and federal regulations – The uses listed below will be conditioned as necessary to protect critical aquifer recharge areas in accordance with the applicable state and federal regulations.

Statutes, Regulations and Guidance Pertaining to Groundwater Impacting Activities

| Activity                                                                                                                                                                                                    | Statute – Regulation – Guidance                                                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|

**19.70.540 Critical Aquifer Recharge Areas – Critical area report additional requirements.**

**A. Additional Report Contents for CARA's.** In addition to the minimum report contents required per AMC 19.70.125 CARA reports must also include;

**B. Minimum Report Contents.** A critical areas report must include a hydrogeologic assessment including, but not limited to, the following:

1. Information sources;
2. Geologic and hydrologic setting including available recharge, permeability/transmissivity information;
3. Available well logs, borings, seeps/springs within 1,000 feet of the project area;
4. Available water quality information;
5. Groundwater depth, flow direction and gradient based on available information;
6. Surface water location and recharge potential;
7. Water source supply to the site;
8. Any sampling schedules necessary;
9. Discussion of the effects of the proposed project on the groundwater resources;

10. Description of potential mitigation measures, should it be determined that the proposed project may have an adverse impact on groundwater resources; and

11. Other information as required by the City.

- C. If the hydrogeologic assessment determines that the facility will have no effect on groundwater resources, the facility is exempt from the development standards requirements in section 19.70.540 of this Chapter.
- D. If the hydrogeologic assessment determines that the facility could have an effect on groundwater resources, the ~~Decision-maker~~ Decision-maker will require implementation of applicable development standards in sections 19.70.540.

---

## **PART 6: FREQUENTLY FLOODED AREAS**

---

### **19.70.610 Frequently Flooded Areas – Description and Purpose.**

- A. Frequently flooded areas perform important hydrologic functions and may present a risk to persons and property.
- B. It is the purpose of this chapter to promote the public health, safety and general welfare, and to minimize public and private losses due to flood conditions in specific areas caused by flooding, while protecting the functions and values of floodplains, including special consideration for anadromous fish habitat in combination with the provisions for Fish and Wildlife Habitat Conservation Areas in this chapter.

### **19.70.615 Frequently Flooded Areas – Designation.**

- A. Frequently flooded areas include those areas established as special flood hazard areas under AMC 19.74 Floodplain Management, including those areas of special flood hazard identified by the Federal Insurance Administration in a scientific and engineering report entitled “The Flood Insurance Study for the City of Anacortes” dated March 17, 2003, and any revisions thereto, with accompanying flood insurance rate maps (FIRM), and any revisions thereto. The best available information for flood hazard area identification as outlined in AMC 19.74 Use of Other Base Flood Data in A and V zones is the basis for regulation until a new FIRM is issued that incorporates the data utilities under AMC 19.74 Use of Other Base Flood Data in A and V zones.
- B. Tsunami hazard areas are designated as geologically hazardous areas per AMC 19.70.410 and are subject to applicable development regulations outlined in AMC 19.70.430.
- C. Climate change and sea level rise are affecting many coastal communities and some within Puget Sound. Applicants are urged to become familiar with potential impacts of climate change and sea level rise if development is proposed near the marine shoreline or associated low-lying areas.

### **19.70.620 Frequently Flooded Areas – Mapping.**

- A. **Reference Only.** The maps and resources cited above are to be used as a guide for the City of Anacortes Planning, Community & Economic Development Department, project applicants, and/or property owners and may be continuously updated as new critical areas are identified. They are a reference and do not provide a final critical area designation.

### **19.70.625 Frequently flooded areas – General Development Standards**

- A. All development proposals must comply with AMC 19.74 Floodplain Management for general and specific flood hazard protection.

- B. Development may not reduce the base flood water storage ability. Construction, grading or other regulated activities that would reduce the flood water storage ability must be mitigated by creating compensatory storage on or off site.
- C. Alteration of Watercourses.
  - 1. Projects that will relocate a watercourse must also submit a request for Conditional Letter of Map Revision, where required by FEMA. The project may not be approved unless FEMA issues the CLOMR (which requires ESA consultation) and the provisions of the letter are made part of the permit requirements.
  - 2. The ~~Decision-maker~~[Decision-maker](#) must notify adjacent communities (if applicable) and the Department of Ecology prior to any alteration or relocation of a watercourse, and submit evidence of such notification to FEMA.
  - 3. Maintenance must be provided within the altered or relocated portion of said watercourse so that flood carrying capacity is not diminished. If the maintenance program does not call for cutting of native vegetation, the system must be oversized at the time of construction to compensate for said vegetation growth or any other natural factor that may need future maintenance.
- D. Base flood data and flood hazard notes must be shown on the face of any recorded plat or binding site plan, including, but not limited to, base flood elevations, flood protection elevation, boundary of floodplain, and zero rise floodway.
- E. All development must conform to the provisions of the currently adopted International Building Code, including submittal of a critical areas report.

#### **19.70.630 Frequently Flooded Areas – Critical Areas Report Additional Requirements**

- A. Additional Report Contents for FFA's. In addition to the minimum report contents required per AMC 19.70.125 FFA reports must also include;
- B. Minimum Report Contents. A critical areas report must include a habitat assessment prepared in accordance with [Regional Guidance for Floodplain Habitat Assessment and Mitigation](#) (FEMA Region X, 2013), or as hereafter amended. The assessment must determine if the project would adversely affect:
  - 1. The primary constituent elements identified when a species is listed as threatened or endangered;
  - 2. Essential fish habitat designated by the National Marine Fisheries Service;
  - 3. Fish and wildlife habitat conservation areas;
  - 4. Vegetation communities and habitat structures;
  - 5. Water quality;

6. Water quantity, including flood and low flow depths, volumes and velocities;
  7. The channel's natural planform pattern and migration processes;
  8. Spawning substrate, if applicable; and/or
  9. Floodplain refugia, if applicable.
- C. If the assessment concludes that the activity is expected to have an adverse effect on water quality and/or aquatic or riparian habitat or habitat functions, the project must be designed in a way to off-set those impacts. Project mitigation ~~will is~~ not ~~be~~ permitted in accordance with Regional Guidance for Floodplain Habitat Assessment and Mitigation, FEMA Region X, 2013.
- D. The following activities do not require completion of a habitat assessment:
1. Repair of existing building in its existing footprint, including damage by fire or other casualties;
  2. Removal of noxious weeds;
  3. Replacement of nonnative vegetation with native vegetation;
  4. Ongoing activities such as lawn and garden maintenance;
  5. Removal of hazard trees;
  6. Normal maintenance of public utilities and facilities;
  7. Restoration or enhancement of floodplains, riparian areas and streams that meets federal and state standards.

---

## DEFINITIONS

---

“Adjacent” means areas adjacent to critical areas must be considered to be within the jurisdiction of these requirements and regulations to support the intent of this title and ensure protection of the functions and values of critical areas. Adjacent must include lands within a distance equal to the required buffer for the critical area as determined by the provisions of this chapter.

“Anadromous fish” means fish that spawn and rear in freshwater and mature in the marine environment. While Pacific salmon die after their first spawning, adult char (bull trout) can live for many years, moving in and out of saltwater and spawning each year. The life history of Pacific salmon and char contains critical periods of time when these fish are more susceptible to environmental and physical damage than at other times. The life history of salmon, for example, contains the following stages: upstream migration of adults, spawning, inter-gravel incubation, rearing, smoltification (the time period needed for juveniles to adjust their body functions to live in the marine environment), downstream migration, and ocean rearing to adults.

“Aquifer” means a body of soil or rock that contains sufficient saturated material to conduct groundwater and yield usable quantities of groundwater to wells or springs.

“Averaging” means establishing the required buffer setback from a critical area, within the permitted parcel of land only, so that areas within the parcel determined to be more environmentally sensitive than others will have a larger buffer than the less sensitive areas. For every increase in setback for one area of the parcel, there will be an equal corresponding decrease in another area of the parcel. The total land area within the buffer must remain the same as if the buffer were a uniform width. “Aquifer” means a body of soil or rock that contains sufficient saturated material to conduct groundwater and yield usable quantities of groundwater to wells or springs.

“Base flood” means a flood having a one percent chance of being equaled or exceeded in any given year, often referred to as the “100-year flood”.

“Base flood elevation” means the water surface elevation of the base flood in relation to the North American Vertical Datum of 1988. The Anacortes FIRMs still make reference to the 1929 National Geodetic Vertical Datum (NGVD). While using NAVD is acceptable, please recognize that surveyors and designers will need to convert the datum when preparing plans. FEMA Elevation Certificates require the use of the datum utilized on the FIRMs.

“Best available science” means current scientific information used in the process to designate, protect, or restore critical areas that is derived from a valid scientific process as defined by WAC 365-195-900 through 925. Sources of best available science are included in “Citations of Recommended Sources of Best Available Science for Designating and Protecting Critical Areas” published by the Washington State Department of Commerce.

“Best management practices (BMPs), critical areas” means physical or structural tools and/or management practices which, when used singularly or in combination, prevent or reduce adverse impacts to critical areas or their buffers.

“Buffer” is an area contiguous to a critical area that is required to protect the critical area and provide for the continued maintenance, functioning, and/or structural stability of a critical area.

“Critical aquifer recharge areas” are areas with a critical recharging effect on aquifers used for potable water, including areas where an aquifer that is a source of drinking water is vulnerable to contamination that would affect the potability of the water, or is susceptible to reduced recharge.

“Critical areas” means critical aquifer recharge areas, fish and wildlife habitat conservation areas, frequently flooded areas, geologically hazardous areas, streams, and wetlands, as defined in this Chapter.

“Development” means any human-made change to improved or unimproved real estate, including but not limited to buildings or other structures, mining, dredging, filling, grading, paving, excavation or drilling operations or storage of equipment or materials.

“Ditches” are artificial drainage features created through purposeful human action, such as irrigation and drainage ditches, grass-lined swales, and canals. Purposeful creation from uplands must be demonstrated through documentation, photographs, statements, and/or other evidence in order to be unregulated by this chapter.

“Enhancement” means an action which increases the functions and values of a stream, wetland, or other critical area or buffer.

“Erosion” means the process by which soil particles are mobilized and transported by natural agents such as wind, rain-splash, frost action or surface water flow.

“Erosion hazard areas” are those areas containing soils which, according to the United States Department of Agriculture Natural Resources Conservation Service Soil Survey Program, may experience significant erosion. Erosion hazard areas also include coastal erosion-prone areas and channel migration zones.

“Federal Emergency Management Agency (FEMA) floodway” means the channel of the stream and that portion of the adjoining floodplain which is necessary to contain and discharge the base flood flow without increasing the base flood elevation more than one foot.

“Fish and wildlife habitat conservation areas” are areas that serve a critical role in sustaining needed habitats and species for the functional integrity of the ecosystem, and which, if altered, may reduce the likelihood that the species will persist over the long term. As defined in AMC 19.70.310.

“Floodway, zero rise” means the channel of a stream and that portion of the adjoining floodplain which is necessary to contain and discharge the base flood flow without any measurable increase in flood height. A measurable increase in base flood height means a calculated upward rise in the base flood elevation, equal to or greater than .01 foot, resulting from a comparison of existing conditions and changed conditions directly attributable to development in the floodplain. This definition is broader than that of the FEMA floodway, but always includes the FEMA floodway. The boundaries of the 100-year floodplain, as shown on the Flood Insurance Study for \_\_\_\_\_, are considered the boundaries of the zero-rise floodway unless otherwise delineated by a critical area study.

“Floodplain” means the total area subject to inundation by the base flood.

“Frequently flooded areas” are lands in the floodplain subject to at least a one percent or greater chance of flooding in any given year, or within areas subject to flooding due to high groundwater, high tides, with strong winds, sea level rise, and extreme weather events resulting from global climate change. These areas include, but are not limited to streams, rivers, lakes, coastal areas, wetlands, and areas where high groundwater forms ponds on the ground surface.

“Functions and values” means the beneficial services provided by critical areas to society, including, but not limited to, improving and maintaining water quality, providing fish and wildlife habitat, supporting terrestrial and aquatic food chains, reducing flooding and erosive flows, wave attenuation, historical or archaeological importance, educational opportunities, and recreation. These beneficial roles are not listed in order of priority.

“Geologically hazardous areas” means areas that because of their susceptibility to erosion, sliding, earthquake, or other geological events, are not suited to the siting of commercial, residential, or industrial development consistent with public health or safety concerns.

“Groundwater” means water in a saturated zone or stratum beneath the surface of the land or below a surface water body.

“Habitats of local importance” designated as fish and wildlife habitat conservation areas include those areas found to be locally important by the City of Anacortes.

“Hazard tree” means any tree determined by an International Society of Arboriculture (ISA)-certified arborist to be a hazard to people or property as a result of a risk assessment conducted according to ISA guiding principles.

“In-lieu-fee program” means an agreement between a regulatory agency (state, federal or local) and a single sponsor, generally a public natural resource agency or non-profit organization. Under an in-lieu-fee agreement, the mitigation sponsor collects funds from an individual or a number of individuals who are required to conduct compensatory mitigation required under a wetland regulatory program. The sponsor may use the funds pooled from multiple permittees to create one or a number of sites under the authority of the agreement to satisfy the permittees’ required mitigation.

“Landslide” means an episodic downslope movement of a mass including, but not limited to, soil, rock or snow.

“Landslide hazard areas” are areas at risk of mass movement due to a combination of geologic, topographic, and hydrologic factors.

“Mine hazard areas” are those areas directly underlain by, adjacent to, or affected by mine workings such as adits, tunnels, drifts, or airshafts, and those areas probable to sink holes, gas releases, or subsidence due to mine workings.

“Mitigation” means the use of any or all of the following actions listed in descending order of preference:

1. Avoiding the impact by not taking a certain action;
2. Minimizing the impact by limiting the degree or magnitude of the action by using appropriate technology or by taking affirmative steps to avoid or reduce the impact;
3. Rectifying the impact by repairing, rehabilitating or restoring the affected critical area or buffer;
4. Reducing or eliminating the impact over time by preserving or maintenance operations during the life of the development proposal;
5. Compensating for the impact by replacing, enhancing or providing substitute critical areas and environments;
6. Monitoring the impact and taking appropriate corrective measures.

“Mitigation” means avoiding, minimizing, or compensating for adverse critical areas impacts, using the sequential order of preference listed in 19.70.130, Mitigation requirements.

“Monitoring” means evaluating the impacts of development proposals on biologic, hydrologic and geologic systems and assessing the performance of required mitigation through the collection and analysis of data for the purpose of understanding and documenting changes in natural ecosystems, functions and features including, but not limited to, gathering baseline data.

“Native Growth Protection Area/ Easement” (NGPA/E) means.....

“Native vegetation” means plant species that occur naturally in a particular region or environment and were present before European colonization.

“Normal Appurtenances” means those structures secondary to a primary use that are common to and do not constitute a special privilege. Examples for residential uses include garages, deck, driveways, utilities, and fences.

“Noxious weed” means any plant which is highly destructive, competitive, or difficult to control by cultural or chemical practices, limited to those plants on the state noxious weed list contained in Chapter [16-750 WAC](#) and those regulated by Skagit County.

Piped stream means.....

“Primary association” means the fundamental link between a species and land or aquatic area where anadromous fish, endangered, threatened or sensitive species breed or feed.

“Prior Notification”

“Repair or maintenance” means an activity that restores the character, scope, size, and design of a serviceable area, structure, or land use to its previously authorized and undamaged condition. Activities that change the character, size, or scope of a project beyond the original design and drain, dredge, fill, flood, or otherwise alter critical areas are not included in this definition.

“Replacement” means.....

“Restoration” means measures taken to restore an altered or damaged natural feature, including: (a) Active steps taken to restore damaged wetlands, streams, protected habitat, or their buffers to the functioning condition that existed prior to an unauthorized alteration; and (b) Actions performed to re-establish structural and functional characteristics of a critical area that have been lost by alteration, past management activities, or catastrophic events.

“Seismic hazard areas” are areas subject to severe risk of damage as a result of earthquake induced ground shaking, slope failure, settlement, soil liquefaction, debris flows, lahars, or tsunamis.

“Shoreline jurisdiction” means.....

“Significant tree” means a deciduous or evergreen tree greater than six inches in diameter at five feet above grade.

“Slope” means an inclined ground surface, the inclination of which is expressed as a ratio or percentage of vertical distance to horizontal distance by the following formula:  $-(\text{vertical distance} / \text{horizontal distance}) \times 100 = \% \text{ Slope}$

“Special Flood Hazard Area” means the land in the floodplain that is subject to a one percent or greater chance of flooding in any given year. Designation on maps always includes the letters A or V.

“Species of local importance” are those species that are of local concern designated by the City due to their population status or their sensitivity to habitat manipulation.

“Stream” means an area where open surface water produces a defined channel or bed, not including irrigation ditches, canals, storm or surface water runoff devices, or other entirely artificial watercourses, unless they are used by salmonids or are used to convey a watercourse naturally occurring prior to construction. A channel or bed need not contain water year-round, provided there is evidence of at least intermittent flow during years of normal rainfall.

“Unavoidable impacts” means adverse impacts that remain after all appropriate and practicable avoidance and minimization has been achieved.

“Volcanic hazard areas” include areas subject to pyroclastic flows, lava flows, and inundation by debris flows, lahars, mudflows, or related flooding from volcanic activity.

“Wetland” or “wetlands” means those areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas. Wetlands do not include those artificial wetlands intentionally created from non-wetland sites, including, but not limited to, irrigation and drainage ditches, grass-lined swales, canals, detention facilities, wastewater treatment facilities, farm ponds, and landscape amenities, or those wetlands created after July 1, 1990, that were unintentionally created as a result of the construction of a road, street, or highway. Wetlands include those artificial wetlands intentionally created from non-wetland areas created to mitigate conversion of wetlands.

“Wetland Mitigation Bank” means a site where wetlands are restored, created, enhanced, or in exceptional circumstances, preserved, expressly for the purpose of providing compensatory mitigation in advance of unavoidable impacts to wetlands or other aquatic resources that typically are unknown at the time of certification to compensate for future, permitted impacts to similar resources.

“Wetland mosaic” means an area with a concentration of multiple small wetlands, in which each patch of wetland is less than one acre; on average, patches are less than 100 feet from each other; and areas delineated as vegetated wetland are more than 50% of the total area of the entire mosaic, including uplands and open water.

# Anacortes Critical Area Regulations

## 2nd Draft Changes

December 11, 2019

The following table lists the changes recommended for the 2<sup>nd</sup> draft the Anacortes Critical Area Regulations resulting from internal staff discussion, legal review, Planning Commission direction, and response to public comments.

| AMC Reference        | Recommended Change                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Body of Text         | <i>Change Required Administratively:</i><br>Grammar, numbering, and code citations will be reviewed and corrected by staff.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 19.12, Definitions   | <i>Change Requested by Public Comment:</i><br>Correction of the definition of Passive Recreation to include the missing section (A, B, C,D) from old definition that was in Title 17 but is no longer in Title 19 definitions.<br><br>Current Language:<br><i>19.12.020: "Passive recreation" means a mix of uses on undeveloped land (including wetland buffers) or minimally improved lands which includes the following: naturally landscaped areas, nonlandscaped green spaces, picnic areas, water bodies, trails, interpretive trails and other similar structures or development.</i><br><br>Options:<br><b>a. Leave definition as is in 19.12.020</b><br><b>b. Correct the definition to match previous 17.06.723</b><br><b>c. Change the definition of Passive Recreation all together.</b>                                                                                                                                                                                                        |
| Staff Recommendation | Staff recommends (option b.) correcting the definition to match the previous definition to read:<br><i>19.12.020 (17.06.723) "Passive recreation" refers to a mix of uses on undeveloped land (including wetland buffers) or minimally improved lands which includes the following: naturally landscaped areas, non-landscaped greenspaces, picnic areas, water bodies, trails, interpretive trails and other similar structures or development.</i><br><br><i>Passive recreation may be defined as a non-motorized activity that:</i><br><i>A. Offers constructive, restorative, and pleasurable human benefits and fosters appreciation and understanding of open space and its purpose;</i><br><i>B. Is compatible with other passive recreation uses;</i><br><i>C. Does not significantly impact natural, cultural, scientific, or agricultural values; and</i><br><i>D. Requires only minimal visitor facilities and services directly related to safety and minimizes passive recreation impacts.</i> |
| 19.12, Definitions   | <i>Change requested by Dept. of Ecology.</i><br>"qualified professional." For wetlands, we [Ecology] recommend:<br><br>A qualified professional for wetlands must be a professional wetland scientist with at least two years of full-time work experience as a wetlands professional, including delineating wetlands                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| AMC Reference           | Recommended Change                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 19.70.035(C)              | <p><i>Change Requested by Staff:</i></p> <p>19.70.035(C) Modifications to Existing Nonconforming Structures and Uses, modified from section 19.70.500 is missing (B) the State Ferry Terminal provision.</p> <p>Current Language:</p> <p><b>C. Modifications to Existing Nonconforming Structures and Uses.</b> Existing structures and uses that were established legally but do not meet the current critical area, buffer, or buffer setback requirements may continue in accordance to AMC 19.49.040, and may be modified as follows:</p> <ol style="list-style-type: none"> <li>1. Routine maintenance and repairs;</li> <li>2. Structural modifications or additions that do not intensify the nonconformity of the structure or increase the area of hardscape lying within the critical area or buffer. The Decision maker may require an updated critical areas report to confirm location of buffers and that the addition is located entirely outside the critical area or buffer;</li> <li>3. Vertical additions above the ground floor that do not encroach further into the critical area or buffer beyond the existing exterior walls, except that critical areas review is required for additions in landslide hazard areas or buffers;</li> <li>4. Restoration or replacement of a structure that is damaged by fire, natural disaster or other calamity when: <ol style="list-style-type: none"> <li>a. A complete application for reconstruction or replacement is submitted within one year of the damage; and</li> <li>b. The restoration or replacement is made to conform to the current critical areas regulations, or if such regulations cannot be physically met without reducing the size of the building, the restoration or replacement may not intensify any nonconformity that existed prior to the damage.</li> <li>c. Except that critical areas review is required for restoration and replacement in landslide hazard areas or buffers.</li> </ol> </li> </ol> <p><b>Options: This is a necessary correction</b></p> |
| Staff Recommendation      | <p>Staff recommends adding the following item #5 to the above section:</p> <ol style="list-style-type: none"> <li>5. State Ferry Terminal. The existing developed footprint, except for infill between the toll booth area in the lowest parking lot, hillside walking paths, and a hillside side slope along the western side of the main terminal parking lot, and including all associated parking, at the Washington State Ferry Terminal facility, shall not be increased and redevelopment may occur provided there is no net loss of ecological function and value in the adjacent buffer areas for Cannery Pond and Ship Harbor Interpretive Preserve wetlands.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 19.70.040 Exemption Table | <p><i>Change Requested by Public Comment:</i></p> <p>Public comment has been received that the Exemption statement “when it can be demonstrated” is confusing, and that the Exemption should not include the term bicycles.</p> <p><b>Passive Outdoor Activities.</b> When it can be demonstrated that there will be no adverse effect, the following activities are allowed within critical areas and their buffers: educational activities,</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Staff Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | <div>Staff recommends (option b.) the all of following changes:</div> <table><tr><th>Permitted Alterations: (Critical Area Permit Required – Type 2 Administrative Decision)</th><th>Critical Area</th><th>Buffer</th></tr><tr><td><p><b>Recreational Areas / Facilities <u>outside of ACFL</u></b> Low impact activities which are consistent with the purpose and function of the critical area buffer and do not detract from its integrity may be permitted within the buffer depending on the sensitivity of the critical area.</p><p>A. Limited public park or public recreational access including <u>but not limited to</u> trails, viewing platforms, fishing access (no wider than 6 foot), and foot bridges, provided that all of the following are satisfied:</p><ul style="list-style-type: none"><li>a. The area/facility is part of a public park that is dependent on its location for recreational function; and</li><li>b. The area/facility is limited to the minimum necessary to accomplish the recreational function; and</li><li>c. The removal of trees and native vegetation is minimized; and</li><li>d. The balance of the development is consistent with other requirements of this chapter; and</li><li>e. The project is identified in the Anacortes Comprehensive Plan or Parks <u>Comprehensive Plan, and ACFL Master Plans.</u></li></ul><p>B. Private pedestrian walkways and public trails must meet the following standards:</p><ul style="list-style-type: none"><li>a. The trail is generally parallel to the perimeter of the critical area;</li><li>b. The trail is located in the outer 25% of the buffer area and is designated to avoid removal of s trees and native vegetation;</li><li>c. The trail does not exceed 6 feet in width, and is limited to native soils or pervious surfaces. Raised boardwalks utilizing non-treated pilings may be acceptable; and</li></ul><p>The trail may be subject to closure during critical spawning, migration or breeding time periods of sensitive species that are present.</p><p>C. Informational signs. Construction and placement of informational signs or educational demonstration facilities no more than 9 square feet surface area and 4 feet high, as long as there is no permanent infringement on hydrology or stream flow <u>and non-treated wood is used;</u></p><p>D. Limited excavating and filling necessary for the repair and maintenance of piers, walkways, observation decks, wildlife management shelters, boathouses, and other similar water related structures, provided they are built on pilings to allow unobstructed flow of water and preserve <u>the natural contour of the wetland, except as authorized by a Critical Area Variance.</u></p></td><td>No</td><td>Yes</td></tr></table> | Permitted Alterations: (Critical Area Permit Required – Type 2 Administrative Decision) | Critical Area | Buffer | <p><b>Recreational Areas / Facilities <u>outside of ACFL</u></b> Low impact activities which are consistent with the purpose and function of the critical area buffer and do not detract from its integrity may be permitted within the buffer depending on the sensitivity of the critical area.</p> <p>A. Limited public park or public recreational access including <u>but not limited to</u> trails, viewing platforms, fishing access (no wider than 6 foot), and foot bridges, provided that all of the following are satisfied:</p> <ul style="list-style-type: none"><li>a. The area/facility is part of a public park that is dependent on its location for recreational function; and</li><li>b. The area/facility is limited to the minimum necessary to accomplish the recreational function; and</li><li>c. The removal of trees and native vegetation is minimized; and</li><li>d. The balance of the development is consistent with other requirements of this chapter; and</li><li>e. The project is identified in the Anacortes Comprehensive Plan or Parks <u>Comprehensive Plan, and ACFL Master Plans.</u></li></ul> <p>B. Private pedestrian walkways and public trails must meet the following standards:</p> <ul style="list-style-type: none"><li>a. The trail is generally parallel to the perimeter of the critical area;</li><li>b. The trail is located in the outer 25% of the buffer area and is designated to avoid removal of s trees and native vegetation;</li><li>c. The trail does not exceed 6 feet in width, and is limited to native soils or pervious surfaces. Raised boardwalks utilizing non-treated pilings may be acceptable; and</li></ul> <p>The trail may be subject to closure during critical spawning, migration or breeding time periods of sensitive species that are present.</p> <p>C.                                                                                                                             | Buffer                                                                                  |               |        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |    |     |
| <p><b>Recreational Areas / Facilities <u>outside of ACFL</u></b> Low impact activities which are consistent with the purpose and function of the critical area buffer and do not detract from its integrity may be permitted within the buffer depending on the sensitivity of the critical area.</p> <p>A. Limited public park or public recreational access including <u>but not limited to</u> trails, viewing platforms, fishing access (no wider than 6 foot), and foot bridges, provided that all of the following are satisfied:</p> <ul style="list-style-type: none"><li>a. The area/facility is part of a public park that is dependent on its location for recreational function; and</li><li>b. The area/facility is limited to the minimum necessary to accomplish the recreational function; and</li><li>c. The removal of trees and native vegetation is minimized; and</li><li>d. The balance of the development is consistent with other requirements of this chapter; and</li><li>e. The project is identified in the Anacortes Comprehensive Plan or Parks <u>Comprehensive Plan, and ACFL Master Plans.</u></li></ul> <p>B. Private pedestrian walkways and public trails must meet the following standards:</p> <ul style="list-style-type: none"><li>a. The trail is generally parallel to the perimeter of the critical area;</li><li>b. The trail is located in the outer 25% of the buffer area and is designated to avoid removal of s trees and native vegetation;</li><li>c. The trail does not exceed 6 feet in width, and is limited to native soils or pervious surfaces. Raised boardwalks utilizing non-treated pilings may be acceptable; and</li></ul> <p>The trail may be subject to closure during critical spawning, migration or breeding time periods of sensitive species that are present.</p> <p>C. Informational signs. Construction and placement of informational signs or educational demonstration facilities no more than 9 square feet surface area and 4 feet high, as long as there is no permanent infringement on hydrology or stream flow <u>and non-treated wood is used;</u></p> <p>D. Limited excavating and filling necessary for the repair and maintenance of piers, walkways, observation decks, wildlife management shelters, boathouses, and other similar water related structures, provided they are built on pilings to allow unobstructed flow of water and preserve <u>the natural contour of the wetland, except as authorized by a Critical Area Variance.</u></p> | No Any other regulated Category II wetland, as rated under subsection (B)(2) of this section, that is within the watersheds of Little Cranberry Lake, Whistle Lake and Heart Lake and that drains by natural seasonal surface water connection into those lakes or their upstream associated wetland systems.</p> <p>D. Locally Significant wetlands. The following wetlands are designated as Category II wetlands regardless of Rating:</p> <p>1. The wetlands on or adjacent to the Port of Anacortes owned property at the Anacortes Airport. Buffers shall conform to the Memorandum of Understanding between the Port and the City until the expiration of the Agreement.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <p>19.70.240<br/>Wetlands –<br/>Specific Wetland<br/>Category<br/>Development<br/>Standard</p> | <p><i>Change requested by Dept of Ecology.</i></p> <p>19.70.240.B.3: The small wetland exemption should be applied to Category IV wetlands only. The draft language includes Category III wetlands. Paragraph 3.d should read, "The wetland is a low quality Category IV wetland with a habitat score of less than 6 points in the adopted rating system. Also "hydrologically isolated" should be replaced with "non-federally regulated," and this definition should be included:</p> <ul style="list-style-type: none"> <li>○ Non-federally Regulated (formerly isolated) Wetland – A wetland that is determined by the United States Army Corps of Engineers (USACE) to not qualify as a Water of the United States. Non-federally regulated wetlands may perform important functions and are protected by state law (RCW 90.48) whether or not they are protected by federal law.</li> </ul> <p>Current Language:</p> <p>3. <i>Small, Hydrologically Isolated Category III and IV Wetlands (less than 1,000 sq. ft.). The Decision maker may allow small, hydrologically isolated Category III and IV wetlands to be exempt from the requirement to avoid impacts (AMC 19.70.135(A)(1) Mitigation requirements) and allow alteration of such wetlands if all of the following conditions are met:</i></p> <ul style="list-style-type: none"> <li>a. <i>The remaining mitigation sequencing actions of AMC 19.70.135(A) (2)-(6) are followed;</i></li> <li>b. <i>The wetland is less than 1,000 square feet in area;</i></li> <li>c. <i>The wetland does not have unique characteristics that would be difficult to replace through standard compensatory mitigation practices.</i></li> <li>d. <i>The wetland is a low quality Category III or IV wetland with a habitat score of less than 5 points in the adopted rating system;</i></li> <li>e. <i>The wetland does not provide significant suitable breeding habitat for native amphibian species. Suitable breeding habitat may be indicated by adequate stable and seasonal inundation that is persistent from February to at least through April and presence of thin-stemmed emergent vegetation and/or clean water;</i></li> <li>f. <i>The wetland does not contain habitat identified as essential for local populations of priority species identified by the Washington Department of Fish and Wildlife or species of local importance which are regulated as fish and wildlife habitat conservation areas in Chapter 19.70.300 (FWHCA section);</i></li> <li>g. <i>The wetland is not associated with shorelines of the state or their associated buffers;</i></li> <li>h. <i>The wetland is not associated with riparian areas or buffers;</i></li> <li>i. <i>The wetland is not part of a wetland mosaic; and</i></li> <li>j. <i>A mitigation plan to replace lost wetland functions and values is developed, approved, and implemented consistent with AMC 19.70.140.</i></li> </ul> |

| AMC Reference                       | Recommended Change                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Staff Recommendation | <p>Staff agrees with Ecology that incentivizing buffer improvements is a good idea. Smaller high functioning buffers are better for critical areas than bigger low functioning buffers. We recommend incorporating Ecology's recommendation to read:</p> <ol style="list-style-type: none"> <li>1. For wetlands that score 6 points or more for habitat function, buffer widths for high intensity may be reduced to moderate intensity if both of the following criteria are met: <ol style="list-style-type: none"> <li>a. A relatively undisturbed, vegetated corridor at least 100 feet wide is protected between the wetland and any other relatively undisturbed area, as defined in the 2014 wetland rating system, or any other Priority Habitat as defined by the Washington State Department of Fish and Wildlife. The latest definitions of Priority Habitats and their locations are available on the WDFW web site at: <a href="http://wdfw.wa.gov/hab/phshabs.htm">http://wdfw.wa.gov/hab/phshabs.htm</a> ). The corridor must be protected for the entire distance between the wetland and the relatively undisturbed area or Priority Habitat by some type of legal protection such as a conservation easement. Presence or absence of a nearby habitat must be confirmed by a qualified biologist.</li> <li>b. The measures in Table XX are implemented, where applicable, to minimize the impacts of the adjacent land uses.</li> </ol> </li> <li>2. For wetlands that score 3-5 habitat points, only the measures in Table XX are required for the use of moderate intensity buffer widths.</li> <li>3. If an applicant chooses <b>not</b> to apply the mitigation measures in Table XX, or is unable to provide a protected corridor where available, then high intensity buffer widths must be used.</li> </ol> <p><b>Table XX Required measures to minimize impacts to wetlands</b><br/>(All measures are required if applicable to a specific proposal)</p> <table border="1" data-bbox="358 1656 1523 1736"> <tr> <th data-bbox="358 1656 626 1696">Disturbance</th><th data-bbox="626 1656 1523 1696">Required Measures to Minimize Impacts</th></tr> <tr> <td data-bbox="358 1696 626 1736">Lights</td><td data-bbox="626 1696 1523 1736"> <ul style="list-style-type: none"> <li>Direct lights away from wetland</li> </ul> </td></tr> </table> | Disturbance | Required Measures to Minimize Impacts | Lights | <ul style="list-style-type: none"> <li>Direct lights away from wetland</li> </ul> |

| Staff Recommendation                  | <p>Staff agrees that context would be helpful and recommends (Option c.) by adding a purpose statement to 19.70.350(C)(1) to read:</p> <p><i>Purpose. The Anacortes Community Forest Lands include three lakes and their watersheds, numerous wetlands, rock bluffs, old growth forests, grassy knolls, windswept hilltops, sheltered caves, and a variety of other habitats and microclimates that provide a unique and irreplaceable habitat for both imperiled and commonplace species. This land has been dedicated by the City for the preservation of forest lands and species, as described in the Conservation Easement documents, the ACFL Comprehensive Plan, and in the newly created Anacortes Municipal Code Title 12.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 19.70.350, FWHCA - Specific Standards | <p><i>Changes requested by Staff and the Skagit Land Trust:</i></p> <p>To keep formatting consistent we propose adding a purpose statement to (C)(2) of this section, March Point Heronry (using existing language in subsection a.) and revisions to the specific standards as recommended by the Skagit Land Trust based on Best Available Science and local knowledge of the habitat needs.</p> <p>Current Language:</p> <p><i>C.2. March Point Heronry</i></p> <p><i>a. Because Skagit County is home to the greatest concentration of nesting Great Blue Heron in the Salish Sea, March Point being the largest, the City has identified the March Point Heronry as a habitat of local importance.</i></p> <p><i>b. Proposed development activities within 1,000 feet, or that is likely to impact the colony, must provide a critical areas assessment report and habitat management plan that follows at a minimum the guidelines provided by WDFW’s Management Recommendations for Washington’s Priority Species (March 2012). <a href="https://wdfw.wa.gov/publications/00026/abbreviated_great_blue_heron.pdf">https://wdfw.wa.gov/publications/00026/abbreviated_great_blue_heron.pdf</a>.</i></p> <p><i>c. Buffers will be implemented as described in the buffer section below.</i></p> <p><i>d. Colony protection is required for minimum 10-years after abandonment.</i></p> <p><b>Options: This is a necessary correction</b></p> |
| Staff Recommendation                  | <p>Staff recommends the subsection read as follows:</p> <p><i>C.2. March Point Heronry</i></p> <p><i>Purpose. Because Skagit County is home to the greatest concentration of nesting Great Blue Heron in the Salish Sea, March Point being the largest, the City has identified the March Point Heronry as a habitat of local importance.</i></p> <p><i>a. Proposed development activities within the 1,000 foot management zone, or that are likely to impact the colony, must provide a critical areas assessment report and habitat management plan that follows at a minimum the guidelines provided by WDFW’s Management Recommendations for Washington’s Priority Species (March 2012).</i></p> <p><i>b. Buffers will be implemented as described in the buffer section below.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Leave Draft 2 as is utilizing the current ACFL provisions,</b></li> <li><b>b. Add the Addendum back into Draft 2,</b></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| AMC Reference        | Recommended Change                                                                                                                                           |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                      | <b>c. Create a new chapter for the ACFL in the Anacortes Municipal Code.</b>                                                                                 |
| Staff Recommendation | Staff recommends adding a section to Title 12, under AMC 12.19 where detailed information about the Anacortes Community Forest Lands can go with Appendix B. |

**From:** [Bruce Baglien](#)  
**To:** [Cooper, Tess](#)  
**Subject:** Landslide areas along the Guemes Channel trail  
**Date:** Thursday, March 18, 2021 10:56:10 AM

---

To whom it may concern,

It appears that the known landslide areas along the paved portion of the Guemes Trail have not been noted in the Geological map. Why is it not noted? Clearly, the housing project that was built above the trail has done damage to the stability of the slope that is very unstable. It should also be noted that the city has had to spend enough money on the problems caused by this housing project and the continual cutting of trees holding the cliff back.

The professional geotechnical engineering study noted these problems. It was also noted there were problems along this portion of the trail related to sea-level rise. These issues should be taken into consideration when it has impacted the city budget as it has.

Sincerely,

Bruce Baglien

In the “Current Draft 3 Documents” published today is the above mentioned Notice. The Notice is dated 3/17/2021 and states that comments must be submitted **on or before 5 PM March 17, 2021**. Likely an inadvertent error as elsewhere it says March 31. The Public Hearing date of April 12 is presumed to be accurate. A response is needed only if the latter date is different. Thanks so much, Kathleen Lorence-Flanagan

**To:** [Cooper, Tess](#)  
**Subject:** SHIP wetland rating  
**Date:** Friday, April 9, 2021 2:39:41 PM

---

Dear Tess,

As you may recall from the comments I made on Draft 2 of the CAO, I have a particular interest in SHIP.

In January 2020, I understood that the Department of Ecology had given SHIP a habitat score of 8 and a total score of 23. By that yardstick, SHIP would remain a Category I wetland under the revised CAO and enjoy an enlarged buffer thanks to the high habitat score.

Would you please confirm my understanding? If possible, I would like to see a copy of the Ecology report.

Best regards,

Neil A. O'Hara

**From:** Andrea Doll <andrea.doll@gmail.com>  
**Sent:** Monday, April 19, 2021 2:13 PM  
**To:** CityClerk  
**Subject:** Critical area comments

My name is Andrea Doll  
I reside at 1319 8th St.  
Anacortes

The intention of the Critical Area Ordinance is to “Protect, maintain and restore healthy, functioning ecosystems through the protection of unique, fragile, and valuable elements of the environment, including, but not limited to wetlands, and fish and wildlife and their habitats, and to conserve the biodiversity of plant and animal species;

But is it?

the draft ordinance offers developers this assurance: “it is not the intent of Chapter to make a parcel of property unusable by denying its owner reasonable economic use of the property..”

The question is: does the ordinance offer EQUAL protection for habitat as it does for property rights?

Through out the CAO draft there are assurances and reassurances: One can skirt environmental restrictions by the use of variances, mitigation and loopholes

Examples:

1. If wetlands are on part of a property the homeowner can encroach on the wetland if it is necessary to add to their residence, i.e. patio, garage
2. If a property has extensive wetlands and streams the developer may build a road through it or relocate a stream in to access a proposed development.
3. A wetland may be filled in for development if a “new wetland” is created elsewhere, the criterion: “no net loss”

People are coming to Anacortes, you can see development every where. It is critical that what we love be protected, not degraded and compromised.

What is YOUR -Anacortes's position. Is it **slogging defense** of the environment or—are you. taking bold steps forward

For example, Are we increasing, not decreasing wet land buffers

Are we inventorying wetlands with an eye to the future

As it stands now:

The CAO as currently written is an invitation to loss, not gain.

I would urge you ,our city council to decide your position, your intent: is it -compromise or bold leadership.

**Subject: Critical Area Ordinance Update -Testimony for April 19, 2021 Critical Area Ordinance Public Hearing - Ian S. Munce, AICP**

Good day,

1. The City's Comprehensive Plan mandates that the Critical Area Ordinance (CAO) Update "... strengthen regulations to protect sensitive naturel areas..." Attachment A. I respectfully submit that with a few minor edits (that I propose) the CAO Update does just this as to new development projects but takes a major step backward as to property owners who may not want to ever develop but take steps to convert wetland and/or wetland buffer into landscaped areas.

2. The standards that apply to new development projects, in my professional opinion, seem entirely appropriate based on current best available science and best planning practices. I particularly appreciate that the baseline for CAO project review as to wetland category will not include illegal encroachments. However, to ensure that buffer encroachments do not lead to reduced buffer delineations at a later date the CAO needs to explicitly state that a wetlands buffer requirement must be based on the pre-violation habitat condition of the wetland. Attachment B (i).

3. I do think that it is essential that baseline dates are spelled out in 19.70, e.g., for wetlands over 10,000 square feet that baseline date is January 10, 1990 (the effective date of the City's first Wetland Ordinance) and for smaller wetlands is April 14, 1994. I suggest that these dates and other critical area baseline dates are so significant that the opening Goal section should be expanded to read "Goals and Baseline Dates". Attachment B (ii).

4. The wetland map included in the draft ordinance seems to largely track the Wetland District map attached to the 1990 Ordinance. Attachment C. The glaring difference is that the 1990 ordinance applied best availability science and designated, mapped, and protected wetlands over 10,000 square feet and the draft ordinance without explanation recategorizes these as "potential wetlands". The 1990 ordinance quite deliberately placed the onus on the property owner to show that they did not have a wetland and not on the City to pursue complex enforcement actions. The draft CAO simply does not address the structural issue I raised with the City Council last fall (Attachment D) and I thought that staff promised a fix. I do not see such a fix in the draft CAO. The City's use of a 'potential wetland' category and a property owner refusal to allow the City to access their property to determine the category and extent of the wetland and wetland buffers apparently ends the City interest and concern for non-project based wetland protection. Absent a major development proposal, either now or in the future, property owners are placed in a voluntary compliance position. This approach falls far short of what the City Comprehensive Plan, the CAO WAC guidelines, the Growth Management Act mandate.

5. Although the code language of the wetland protection ordinance has been updated since 1990 to the best of my knowledge the 1990 map has never been repealed and is still 'on file' and referenced in the current language of the City Municipal Code. It simply disappears in the proposed new CAO. It should be retained. Attachment B(iii), (iv), and (v). In the alternate the CAO could simply solve the structural problem by specifying that if a property owner denies the

City access for wetland delineation purposes, then the City defaults to Attachment C and takes appropriate enforcement action.

6. Given the Comprehensive plan policies set forth in Attachment A flooding concerns should be expanded to “excess stormwater and/or flooding”, neighbors should be consulted on enforcement actions, and penalties for violations should be mandatory. Attachment B(vi), (vii), and (viii).

7. The recitals in the Ordinance should include key Comprehensive Plan policies cited in Attachment A. Attachment B (ix).

8. Progressive jurisdictions such as Anacortes typically integrate critical area management into their stormwater management programs and this will be essential to achieving the Comprehensive Plan policies set forth in Attachment A. Attachment B (x).

9. Simply assuming that reasonable use variances will be granted and wetlands and wetland buffer will be encroached upon is contrary to the Comprehensive Plan policies set forth in Attachment A. Again, progressive jurisdictions such as Anacortes are putting in place Transfer of Development Rights programs with sufficient incentives to minimize the need for critical area reasonable use variances”. Attachment B (xi).

## PROPOSED EDITS TO JANUARY 2, 2021 DRAFT AMC 19.70 CRITICAL AREA ORDINANCE AND REGULATIONS—Ian Munce, AICP

(i) **Chapter 19.70.235 Wetlands—Required Buffer Areas (A) Buffer Requirements:** Add a #3 “Illegal Modifications. When a violation occurs buffer requirements do not change due to illegal modifications or alterations. A wetlands buffer requirement must be based on the pre-violation habitat condition of the wetland”.

(ii) **Chapter 19.70.010: Expand the heading “Purpose” to “Purpose and Baseline Dates”.**

(iv) **“Wetlands over 10,000 square feet** have been designated, mapped, protected, and regulated since January 15’ 1990 (Ordinance No.2131), geological hazardous areas have been protected and regulated since September 2, 1991 (Ordinance No. 2198), frequently flooded areas protected and regulated since May 19, 2003 (Ordinance No. 2617) and aquifer recharge areas protected and regulated since September 29, 2003 (Ordinance No. 2628). These dates are critical to determinations as to review of new development applications, potential violations, rating categories under 19.70.020, modifications under 19.70.035, exemptions under 19.70.040, and illegal modifications under 19.70.215”.

(iii) **Chapter 19.70.220 Wetlands—Mapping and Delineation (A) Mapping:** Add after the first sentence: “This layer includes the map adopted by Ordinance # 2131, January 15, 1990”. (B) Reference Only: insert at the beginning of the first sentence: “Except for the map adopted by Ordinance # 2131, ... and add at the end of the sentence “through the Annual Development Regulation Amendment process”.

(iv) **Chapter 19.70.020 Identification, classification, and rating of critical areas:** Add after the first sentence “These maps include the map adopted by Ordinance # 2131, January 15, 1990”. Add at the end of the second sentence “except that the map adopted by Ordinance # 2131 actually locates the presence of wetlands over 10,000 square feet”. Add to the final sentence “through the Annual Development Regulation Amendment process”.

(v) **“Chapter 19.70.220 Wetlands—Mapping and Delineation:** Wetlands over 10,000 square feet have been designated, mapped, protected, and regulated since January 15’ 1990 (Ordinance No.2131), geological hazardous areas have been protected and regulated since September 2, 1991 (Ordinance No. 2198), frequently flooded areas protected and regulated since May 19, 2003 (Ordinance No. 2617) and aquifer recharge areas protected and regulated since September 29, 2003 (Ordinance No. 2628). These dates are critical to determinations as to review of new development applications, potential violations, rating categories under 19.70.020, modifications under 19.70.035, exemptions under 19.70.040, and illegal modifications under 19.70.215”.

(vi) **Chapter 19.70.010:** protect not just from “flooding” but from “excess stormwater and/or flooding”.

(vii) **Chapter 19.70.010:** In the current final square remove “or enforcement” from the first sentence and add a second sentence “Neighbors adversely affected by an illegal activity shall be consulted by the City before any final enforcement decision is reached and implemented”.

## ATTACHMENT B

(VIII) Chapter 19.70.165 E Penalties: Change the permissive language to mandatory language "...shall be subject" ...".

(IX)) ORDINANCE: Insert Comprehensive Plan Policies from Attachment A.

(x) ORDINANCE: Add a Section 2: "Stormwater Management funds may be used, as appropriate, to implement the Comprehensive Plan critical area policies recited above; this is essential to restoration efforts".

(xi) ORDINANCE: Add a Section 3: "A Transfer of Development Rights program shall be established with sufficient incentives to minimize the need for critical area reasonable use variances".

Subject: Public Comment for August 24 Council Meeting Item 5d: "Designating" Critical Areas

Good day, Mayor and City Councilmembers

I apologize for not being clear in my public comments last week.

When I said there was a structural problem with the draft ordinance I did not mean a definitional problem as to what constitutes development. I was referring to the practical reality that if a property owner needs a development permit from the City, then they have to meet all ordinance requirements to the satisfaction of City staff. However, if you go forward with a simple "potential wetland" designation then if a property owner asserts that they are just undertaking "pre-1990 maintenance" vegetation removal on a "suspected wetland" and denies City access to the property (pursuant to your current draft section 19.70.170 D) then only an expensive and multi-year court battle can remedy the alleged violation.

This is why I respectfully urge the City Council to retain the current mapped designations for wetlands over 10,000 square feet. This designation was done initially by ordinance in 1990 to give the City immediate enforcement authority over valuable wetlands.

Given this structural problem and the strong environmental protection policies set forth in your Comprehensive Plan you might wish to "designate" key components of other critical areas under consideration on August 24.

Thank you.

Ian Munce, J.D., AICP

# CRITICAL AREA MANDATES

## CITY ANACORTES

### COMPREHENSIVE PLAN, 2015

#### ATTACHMENT A

#### EMPHASIS ADDED IN BOLD

---

## VISION STATEMENT

ANACORTES IS A UNIQUE, CREATIVE, AND CARING MARITIME COMMUNITY THAT ... PROTECTS OUR NATURAL ENVIRONMENT ... FOR FUTURE GENERATIONS

VALUES STATEMENTS/Pursue Environmental Sustainability: embrace a conservation ethic, develop and maintain healthy land and marine ecosystems, and adopt innovative and environmentally sensitive development practices.

Land Use Goal LU-4. Resource protection and sustainable design. Maintain and **strengthen** regulations to protect sensitive natural areas and pursue strategies/actions to **restore** degraded natural areas.

Environment and Conservation Goal EC-1 Environmental protection. Serve as a **leader** in environmental stewardship of the natural environment for current and future generations.

Policy EC-1.2 Work cooperatively with local, state, regional, and federal governments and **community organizations** to protect and **enhance** the environment.

Policy EC-1.8 Use the best available science to preserve or enhance the function and values of critical areas through regulations, programs, and incentives.

Policy EC-3.3 Promote soil stability through **retention of existing vegetation**.

Environment and Conservation Goal EC-4 Water Quality. Protect and **enhance** water quality.

Policy EC-4.1 Work with neighboring jurisdictions, **citizens, and other partners** to maintain and **restore** natural hydrological functions in a drainage basin ....

Policy EC-4.8 Protect and preserve areas that are critical for aquifer recharge, such as **wetlands**, streams, and water bodies.

Policy EC 4.9 Strive for “no net loss” of wetland acreage, function, and value within each drainage basin over the long term.

Environment and Conservation Goal EC-6. Surface Water. Maintain or improve the functional integrity of watercourses, **wetlands**, bodies of water and their shores.

Policy EC-6.2 Streams and **wetlands should be maintained in their existing natural condition**, or restored where appropriate.

Policy EC-6.5. Place appropriate restrictions on land surface modifications that would cause unnecessarily landscape scarring, hydrology modifications, erosion, or undermining of support of nearby land including, but not limited to, dredging, filling, clearing, paving, and grading.

# ATTACHMENT B

## PROPOSED EDITS TO JANUARY 2, 2021 DRAFT AMC 19.70 CRITICAL AREA ORDINANCE AND REGULATIONS—Ian Munce, AICP

(i) **Chapter 19.70.235 Wetlands—Required Buffer Areas (A) Buffer Requirements:** Add a #3 “Illegal Modifications. When a violation occurs buffer requirements do not change due to illegal modifications or alterations. A wetlands buffer requirement must be based on the pre-violation habitat condition of the wetland”.

(ii) **Chapter 19.70.010: Expand the heading “Purpose” to “Purpose and Baseline Dates”.**

(iv) **“Wetlands over 10,000 square feet** have been designated, mapped, protected, and regulated since January 15’ 1990 (Ordinance No.2131), geological hazardous areas have been protected and regulated since September 2, 1991 (Ordinance No. 2198), frequently flooded areas protected and regulated since May 19, 2003 (Ordinance No. 2617) and aquifer recharge areas protected and regulated since September 29, 2003 (Ordinance No. 2628). These dates are critical to determinations as to review of new development applications, potential violations, rating categories under 19.70.020, modifications under 19.70.035, exemptions under 19.70.040, and illegal modifications under 19.70.215”.

(iii) **Chapter 19.70.220 Wetlands—Mapping and Delineation (A) Mapping:** Add after the first sentence: “This layer includes the map adopted by Ordinance # 2131, January 15, 1990”. (B) Reference Only: insert at the beginning of the first sentence: “Except for the map adopted by Ordinance # 2131, ... and add at the end of the sentence “through the Annual Development Regulation Amendment process”.

(iv) **Chapter 19.70.020 Identification, classification, and rating of critical areas:** Add after the first sentence “These maps include the map adopted by Ordinance # 2131, January 15, 1990”. Add at the end of the second sentence “except that the map adopted by Ordinance # 2131 actually locates the presence of wetlands over 10,000 square feet”. Add to the final sentence “through the Annual Development Regulation Amendment process”.

(v) **“Chapter 19.70.220 Wetlands—Mapping and Delineation:** Wetlands over 10,000 square feet have been designated, mapped, protected, and regulated since January 15’ 1990 (Ordinance No.2131), geological hazardous areas have been protected and regulated since September 2, 1991 (Ordinance No. 2198), frequently flooded areas protected and regulated since May 19, 2003 (Ordinance No. 2617) and aquifer recharge areas protected and regulated since September 29, 2003 (Ordinance No. 2628). These dates are critical to determinations as to review of new development applications, potential violations, rating categories under 19.70.020, modifications under 19.70.035, exemptions under 19.70.040, and illegal modifications under 19.70.215”.

(vi) **Chapter 19.70.010:** protect not just from “flooding” but from “excess stormwater and/or flooding”.

(vii) **Chapter 19.70.010:** In the current final square remove “or enforcement” from the first sentence and add a second sentence “Neighbors adversely affected by an illegal activity shall be consulted by the City before any final enforcement decision is reached and implemented”.

## ATTACHMENT B

(VIII) Chapter 19.70.165 E Penalties: Change the permissive language to mandatory language "...shall be subject" ...".

(IX)) ORDINANCE: Insert Comprehensive Plan Policies from Attachment A.

(x) ORDINANCE: Add a Section 2: "Stormwater Management funds may be used, as appropriate, to implement the Comprehensive Plan critical area policies recited above; this is essential to restoration efforts".

(xi) ORDINANCE: Add a Section 3: "A Transfer of Development Rights program shall be established with sufficient incentives to minimize the need for critical area reasonable use variances".

Subject: Public Comment for August 24 Council Meeting Item 5d: "Designating" Critical Areas

Good day, Mayor and City Councilmembers

I apologize for not being clear in my public comments last week.

When I said there was a structural problem with the draft ordinance I did not mean a definitional problem as to what constitutes development. I was referring to the practical reality that if a property owner needs a development permit from the City, then they have to meet all ordinance requirements to the satisfaction of City staff. However, if you go forward with a simple "potential wetland" designation then if a property owner asserts that they are just undertaking "pre-1990 maintenance" vegetation removal on a "suspected wetland" and denies City access to the property (pursuant to your current draft section 19.70.170 D) then only an expensive and multi-year court battle can remedy the alleged violation.

This is why I respectfully urge the City Council to retain the current mapped designations for wetlands over 10,000 square feet. This designation was done initially by ordinance in 1990 to give the City immediate enforcement authority over valuable wetlands.

Given this structural problem and the strong environmental protection policies set forth in your Comprehensive Plan you might wish to "designate" key components of other critical areas under consideration on August 24.

Thank you.

Ian Munce, J.D., AICP

Re: PLN-2019-0010: Evergreen Islands Comments – 3rd Draft of the City of Anacortes  
Critical Areas Ordinance Update

Dear Ms. Cooper,

I'm writing this letter on behalf of Evergreen Islands ("Evergreen") to request that the City of Anacortes ("City") revise the 3rd Draft of its Critical Areas Regulations ("3rd Draft") consistent with the Growth Management Act's ("GMA") requirement to protect the functions and values of critical areas and to include the Best Available Science ("BAS"). For decades, Evergreen has dedicated itself to promoting, protecting, and defending Skagit County's unique saltwater island ecosystems, and to ensuring that Anacortes manage the expansion of its built environment protect local ecological treasures. Evergreen provides the comments below to continue to advocate for broadly popular actions like the preservation of regionally important spaces like the Ship Harbor wetland, Anacortes Community Forest Lands, and the many local streams. The group welcomes the opportunity to sit down with City representatives to discuss and address these concerns.

These comments are organized as follows:

**Section A** – table identifying recommended language changes;

**Section B** – discussion of the GMA requirement to protect the functions and values of critical areas;

**Section C** – discussion of the GMA requirement to include the BAS;

**Section D** – discussion of the myth of mitigation, summarizing studies demonstrating that compensatory mitigation efforts typically are unsuccessful; and

**Section E** – analysis supporting the revisions recommended in Table A.

**A. Table of Recommended Revisions.**

The table below shows revisions recommended to satisfy GMA requirements as explained at Section E below. Revisions are identified with redlining, with language to be removed shown in strike-through and language to be added shown in underline.

| Section                                                                                      | Page | Draft Text                                                                                                                                                                                                                                                                                                                                                        | Recommended Revision                                                                                                                                                                                                                                                                                                                                                        |

**B. The GMA Requires Cities to Protect the Functions and Values of Critical Areas.**

In 1990, the Legislature adopted the GMA to address uncoordinated and unplanned growth that threatened the environment, sustainable economic development, and the health, safety, and high quality of life enjoyed by Washington residents.<sup>1</sup> A keystone of the GMA structure is the mandate to protect critical areas. The Legislature emphasized the fundamental importance of protecting CAs by requiring cities to designate and protect critical areas before addressing any other GMA mandate.<sup>2</sup> The Board has noted that “[i]t is significant that the [GMA] required cities and counties to identify and conserve resource lands and to identify and protect CAs before the date that [interim Urban Growth Areas] had to be adopted. This sequence illustrates the fundamental axiom of growth management: ‘the land speaks first.’”<sup>3</sup> This primacy “underscores the paramount importance that [the legislature] intended for this statutory mandate.”<sup>4</sup> In Pilchuck, the Board recognized the “higher order of directiveness” and “higher order of urgency” that the legislature placed on CAs, and that “[e]ven the legislature’s choice of the term ‘critical’ to describe these areas conveys an importance greater than, for example, ‘natural systems’ or ‘environmentally sensitive’ areas.”<sup>5</sup>

The GMA’s planning goals and express requirements reflect this substantial concern for protecting CAs. Planning goals 9 and 10 set forth goals to: “retain open space, enhance recreational opportunities, conserve fish and wildlife habitat, increase access to natural resource lands and water, and develop parks and recreation facilities” and “[p]rotect the environment and enhance the state’s high quality of life, including air and water quality, and the availability of water.”<sup>6</sup> The GMA then directs cities to designate CAs, adopt development regulations that protect them, and update those regulations regularly.<sup>7</sup>

The GMA requires the protection of all functions and values of critical areas.<sup>8</sup> Protection means the “preservation of the functions and values of the natural environment or safeguarding the public from hazards to health and safety.”<sup>9</sup> Hence, the court in WEAN struck

stream buffers sized solely for water quality, rather than the “entirety of functions attributed to stream buffers,” because the regulations had not protected “all functions and values” of CAs.<sup>10</sup> And although a city need not maintain all individuals of all species at all times, the “goal of fish and wildlife habitat conservation is to manage land so as to maintain species in suitable habitats within their natural geographic distribution” and avoid creating isolated subpopulations.<sup>11</sup> Thus, “local governments must either be certain that their critical areas regulations will prevent harm or be prepared to recognize and respond effectively to any unforeseen harm that arises.”<sup>12</sup>

### **C. BAS Must Be Included.**

In 1995, the Legislature added the requirement that counties “include the best available science in developing policies and development regulations to protect the function and values of critical areas.”<sup>13</sup> Counties must also “give special consideration to conservation or protection measures necessary to preserve or enhance anadromous fisheries.”<sup>14</sup> The purpose of the BAS requirement is to ensure that CA regulations are based on meaningful, reliable, and relevant evidence, rather than speculation or surmise.<sup>15</sup>

To include BAS, a city must both: (1) gather or develop valid scientific information produced by a scientific methodology; and (2) analyze that information in a reasoned process.<sup>16</sup> Valid scientific information typically bears the following hallmarks: (1) peer review; (2) replicable methods that reach logical conclusions; and (3) appropriate statistical or quantitative methods.<sup>17</sup>

A city includes BAS by identifying: (1) the specific regulations adopted to protect the CA; (2) the relevant sources of BAS included in the decision-making; and (3) any nonscientific information in the record used to justify a departure from BAS recommendations, as well as the rationale, potential risks, and measures to limit risks associated with that departure.<sup>18</sup> A city’s record must show that it considered the BAS substantively in designating and protecting critical

<sup>18</sup> WAC 365-195-915.

areas.<sup>19</sup> Although a city may balance the BAS with GMA goals, it ultimately must protect critical areas.<sup>20</sup>

BAS plays a central role in adopting provisions that protect CAs.<sup>21</sup> In HEAL, the court stated that

[w]hile the balancing of the many factors and goals could mean the scientific evidence does not play a major role in the final policy in some GMA contexts, it is hard to imagine in the context of critical areas. The policies at issue here deal with critical areas, which are deemed “critical” because they may be more susceptible to damage from development. The nature and extent of this susceptibility is a uniquely scientific inquiry. It is one in which the best available science is essential to an accurate decision about what policies and regulations are necessary to mitigate and will in fact mitigate the environmental effects of new development.<sup>22</sup>

Regulations that seek to apply a jurisdiction’s unique view of the science typically contravene the GMA. For example, in Ferry County, the county’s CAO violated the GMA when the county relied on advice from a consultant who did not visit the county and who cited only a 1997 birding manual and a discussion with a wildlife biologist about pygmy rabbits.<sup>23</sup> The county had not vetted the information provided by the consultant or compared it to science from state, federal, and Tribal agencies.<sup>24</sup> The court noted that “a ‘[c]ounty cannot choose its own science over all other science and cannot use outdated science to supports its choice.’”<sup>25</sup> Similarly, in Department of Ecology v. City of Kent, Kent failed to conduct a reasoned analysis when it declined Ecology’s science-based wetlands rating system in favor of an outdated, 1979 wetland classification system that relied upon wetland size and number of vegetation classes without determining wetland functions.<sup>26</sup>

Lastly, when scientific evidence is unavailable, a city should adopt a precautionary or no risk approach.<sup>27</sup> In Yakima County, the court held that Yakima County failed to use a no-risk approach when it responded to scientific uncertainty with minimal stream buffers.<sup>28</sup> Similarly,

<sup>28</sup> 168 Wn. App. at 693.

in Swinomish Indian Tribal Community, the court declared that “local governments must either be certain that their critical area regulations will prevent harm or be prepared to recognize and respond effectively to any unforeseen harm that arises.”<sup>29</sup>

As explained at Section E below, the City has failed to include the BAS in proposing several provisions in its CAO update, including the undersized wetland and stream buffers and the authorization to entirely relocate streams.

**D. Alterations of Critical Areas and Buffers Must Be Strictly Limited Because Compensatory Mitigation Typically Fails to Replace Lost Critical Area Functions.**

The BAS demonstrates that mitigation projects rarely replace lost critical area functions and values and that the best approach to protecting them is to prevent their alteration. Twenty-five years ago, Race and Fonseca synthesized surveys of mitigation projects and found significantly flawed mitigation projects that: (1) did not adhere to established mitigation policies; (2) were frequently unsuccessful; and (3) often missed the deadline.<sup>30</sup> Race and Fonseca stated that “[t]here is need to acknowledge the extent to which non-scientific, real-world complications plague current policies and practices.”<sup>31</sup> Another broad survey of structural and functional loss in restored wetlands found that after 100 years, 621 wetland sites continued to suffer biological structure and biogeochemical functioning 26% and 23% below reference sites.<sup>32</sup> And a 2008 study of 23 wetland mitigation projects found similarly that: (1) 67% of the projects did not meet permit requirements for wetland areas; (2) open-water/emergent wetlands were exchanged for scrub/shrub forested wetlands; (3) wetlands decreased in number from 134 to 65; and (4) smaller wetlands were lost.<sup>33</sup>

Last, a 2009 paper examined the reasons that biodiversity trading programs like critical areas compensatory mitigation provisions fail to achieve no-net-loss and found that such programs can succeed where the trade involves a simple, relatively measurable commodity, like sulfur dioxide in the air, but that they fail when attempting to trade biodiversity like wetland or riparian ecosystems because of their complexity, difficulty in measuring their functions, and

lack of directly interchangeable parts.<sup>34</sup> Particularly pertinent here, the authors conclude that,

given the option of saying to developers ‘yes, with conditions’ rather than ‘no,’ officials will prefer ‘yes, with conditions’ – particularly where compliance with conditions cannot be credibly measured and officials can avoid accountability for outcomes. Legitimized bartering can thus create a policy situation ‘obscure enough to please all parties...and so ill-defined that failures...will be difficult to detect and impossible to litigate.’ ...In sum, while compensation and no net loss are worthy goals, and bartering biodiversity might appear more promising than simple and weakly enforced prohibitions, this article suggests policies that enable biodiversity trading may perversely yield worse biodiversity outcomes.<sup>35</sup>

This inability to ensure the replacement of complex ecosystems impacted by development warrants a greater emphasis on preventing development that would harm critical areas.

#### **E. Several Provisions Must Be Revised to Protects the Functions and Values of Critical Areas.**

In order to organize specific comments around the Best Available Science, the sections below address specific CAO provisions by topic, including: (1) undersized wetland and stream buffers; (2) buffer reductions and averaging; (3) stream relocation; (4) elimination of smaller wetlands; (5) broadly authorized alterations to critical areas; (6) exceptions for activities in critical areas or buffers; and (7) final points. The sections below explain how the BAS supports the text revisions identified in the table at Section A above.

##### **1. Undersized wetland and stream buffers.**

The CAO would set buffers for some wetlands and all streams below the size recommended by the BAS. The City’s consultant and Ecology recommend buffers of a minimum size of 60 feet for Category III wetlands and 40 feet for Category IV wetlands even if required measures are implemented to minimize impacts on wetlands.<sup>36</sup> Yet Table 19.70.235(C) at page 42 of the CAO would establish a 25-foot buffer for Category IV wetlands near low intensity development.<sup>37</sup> Table 19.70.235(D) would set Category III buffers for low intensity development at 40 feet and Category IV buffers at 25 feet for low intensity development.<sup>38</sup> In addition, Ecology’s BAS recommends that Category III wetlands have the same buffer size as Category I and II

<sup>37</sup> CAO Draft 3, at 42.

<sup>38</sup> CAO Draft 3, at 42.

wetlands if they score 5 or more on the habitat score.<sup>39</sup> And Ecology recommends that wetlands with a habitat score of 5 receive a buffer width greater than those that score 3-4, but the City applies the same lower buffer size to wetlands with a score of 5 as it does to wetlands with scores of 3-4.<sup>40</sup> The 3rd Draft's widths should be amended consistent with the BAS for protecting wetlands, which already represent a moderate risk approach that has a medium chance of harming wetlands. In addition to the revisions identified in the table at Section A above, the 3rd Draft should be revised with a table for wetlands with a score of 5 points consistent with Ecology's BAS at pages 28-30 of its Guidance.<sup>41</sup>

With regard to streams, the BAS from the Washington Department of Fish and Wildlife ("WDFW") identifies a need to protect a zone larger than the 50 feet on either side of streams that the CAO proposes.<sup>42</sup> Based on BAS, WDFW categorizes an area called a riparian management zone ("RMZ") as a Priority Habitat and thus recommends that local jurisdictions designate it as a Fish and Wildlife Habitat Conservation Area in their critical areas ordinances.<sup>43</sup> The RMZ is the "area that provides full ecological function for bank stability, shade, pollution removal, contributions of detrital nutrients, and recruitment of large woody debris, and can also provide habitat for terrestrial wildlife species."<sup>44</sup> As indicated by WDFW's recommendation to designate the RMZ as a critical area, it is distinct from a buffer or setback. To protect RMZs, WDFW notes that the BAS contemplates that a CAO will: (1) designate riparian ecosystems as critical areas within an area called the riparian management zone ("RMZ"); (2) include watershed-scale management considerations; (3) establish the width of an RMZ as one site-potential tree height in forested ecoregions like that in which Anacortes is found; (4) consider the needs of relevant terrestrial species; and (5) apply the same RMZ area to all streams, whether or not they are fish-bearing.<sup>45</sup>

WDFW recommends applying the same RMZ protection to all streams because they "found no evidence that full riparian ecosystem functions along non-fish-bearing streams are less important to aquatic ecosystems than full riparian ecosystem functions along fish-bearing streams."<sup>46</sup> In addition, WDFW found that non-fish-bearing streams: (1) support a unique community of aquatic and riparian-obligate wildlife; (2) provide movement corridors for wildlife, particularly in the face of changing climate conditions; (3) provision fish-bearing streams with

matter and energy; and (4) provide cool water to downstream reaches.<sup>47</sup>

Based on the map of site-potential tree height that WDFW has created, the RMZ for streams in Anacortes would extend from approximately 127 feet to 171 feet, consistent with the tree heights there.<sup>48</sup> Within that zone, WDFW recommends avoiding: (1) clearing, grading, and filling; (2) new development that would require bank hardening; (3) on-site sewage systems without habitat monitoring plans; or (4) removal of hazard trees without proper evaluation and avoidance and minimization of impacts.<sup>49</sup> In addition, WDFW notes that its recommendations for RMZs apply to urban areas as well as non-urban areas.<sup>50</sup>

WDFW's recommendations are consistent with the earlier science referenced by the October 21, 2019 document that the City's consultant, GeoEngineers, provided regarding stream buffers (though not with GeoEngineers' ultimate recommendation for 50-foot buffers).<sup>51</sup> Although that document suggests that "a 50-foot buffer is the minimum required to provide a basic level of functions," it overlooks the fact that the studies it references find significantly larger buffers necessary to remove significant amounts of pollutants or to provide habitat.<sup>52</sup> Thus, as acknowledged by that paper, Mayer et al. projected that a 90-foot buffer was needed to remove 75% of nitrogen and a 370-foot buffer for 90% nitrogen removal.<sup>53</sup> Likewise, "[m]ost studies report a range of 200 to 300 feet necessary to provide essential habitat for most wildlife species (Keller et al., 1993)."<sup>54</sup>

The 3rd Draft should be revised consistent with the Ecology and WDFW BAS, including increased wetland buffers and stream RMZs with widths consistent with site-potential tree height, as well as development proscriptions within the RMZs.

## **2. Buffer reductions and averaging.**

The BAS does not support the City's proposed buffer reductions, or its buffer averaging that would unnecessarily reduce portions of a buffer below 75% of its standard width. Section 19.70.235.D of the 3rd draft, at page 43, proposes to reduce wetland buffers based largely on implementing basic recommendations that already apply for the City's buffer sizes, and Section

<sup>54</sup> GeoEngineers, at 10.

19.70.330.C, at pages 63-64, proposes to reduce buffers to 25 or 35 feet if a developer decides they want to reduce buffers and designs a site plan to do so. These sections should be revised consistent with BAS.

In describing the importance of buffers, Ecology's most recent version of its wetlands guidance states that, "[t]he scientific literature is unequivocal that **buffers are necessary to protect wetland functions** and values."<sup>55</sup> As noted above, Ecology's buffer approach are based on a moderate-risk approach with a medium likelihood of causing impacts. Nonetheless, "**Ecology's buffer recommendations are also based on the assumption that the buffer is well vegetated with native species appropriate to the ecoregion.**"<sup>56</sup> Where the buffer does not contain vegetation adequate to protect the wetland functions, it should either be planted or increased in size.<sup>57</sup>

Against this backdrop, Ecology's BAS contemplates buffer averaging in those limited instances where it "will improve the protection of wetland functions, or if it is the only way to allow for reasonable use of a parcel."<sup>58</sup> In addition "[t]he width of the buffer at any given point after averaging should be no smaller than 75% of the standard buffer."<sup>59</sup>

Consequently, the averaging provisions that allow a buffer just 50% should be revised to 75% and averaging where habitat functions will be maintained must be revised to require an improvement.

The extensive buffer reduction allowed through averaging is also inconsistent with the Growth Board's decision in ReSources, Inc. v. City of Blaine, where it rejected buffer averaging that allowed reductions of 40% and 60%, even where "all anticipated impacts to the critical area and its required buffer have been mitigated and, for averaging, the total buffer area is not reduced below the area that would result from use of the standard buffer."<sup>60</sup> The Board noted the lack of BAS to justify the buffer reductions, and quoted with approval Ecology recommendations that

[t]he widths of buffers may be averaged if this will improve the protection of wetland functions, or if it is the only way to allow for reasonable use of a parcel. There is no scientific information available to determine if averaging the widths of buffers actually protects functions of wetlands."<sup>61</sup>

<sup>58</sup> Id. (emphasis added).

<sup>59</sup> Id. (emphasis added).

<sup>60</sup> WWGMHB No. 09-2-0015, FDO, 17 (March 29, 2010).

<sup>61</sup> Id. (emphasis in original)

In addition, no BAS supports merely reducing buffers. For example, there is no support for the proposal to reduce stream buffers to 35 feet or 25 feet where a developer creates a site design that would require such a buffer reduction, as proposed by Section 19.70.330.C on page 63. Nor does the BAS support the proposed wetland buffer reductions based on the implementation of basic minimization measures like addressing lights, noise, toxic runoff, stormwater runoff, change in water regime, pets and human disturbance, and dust, unless the buffer sizes proposed by the City match those recommended by Ecology. The wetland buffer sizes established at Tables 19.70.235(C) and (D) set buffers smaller than Ecology's recommended buffers at Table XX.1 for wetlands that have a habitat score of 5 or 6-7.<sup>62</sup> The 3rd draft CAO chart should be revised for consistency with Ecology recommendations or the buffer reductions must be removed.

### **3. Stream relocation.**

There is no BAS to support the relocation of streams, either as part of a mitigation or rehabilitation/restoration plan or for other purposes. As discussed above, WDFW's Riparian Recommendations demonstrate that riparian corridors must be protected, not moved. Nor is there any BAS that suggests that streams can be moved while protecting their functions and values. On the contrary, WDFW's Riparian Recommendations state that "[t]he use of the precautionary principle and adaptive management are particularly appropriate when dealing with complex and dynamic systems, and when we have uncertainty related to exactly how management activities affect functioning of wetlands and riparian ecosystems."<sup>63</sup> And "[r]iparian areas and surrounding watersheds are complex and dynamic systems comprised of many interacting components."<sup>64</sup> Consequently, the permission to physically relocate streams granted by proposed Section 19.70.330.F. must be removed.

### **4. Elimination of smaller wetlands.**

It is not possible to protect the functions and values of a wetland by allowing it to be destroyed, yet the 3rd Draft would allow the "alteration" of Category IV wetlands up to 1,000 square feet in size at Section 19.70.230.B.3. While one of the conditions contemplates the application of the mitigation sequence, the BAS identified above demonstrates that wetlands are sufficiently complex ecosystems that attempts to mitigate for impacts to them regularly fail. Consequently, this exemption allowing impacts must be repealed.

Further, Growth Board decisions have repeatedly recognized the importance of

---

<sup>62</sup> ECY Guidance, at 26.

<sup>63</sup> Riparian Recommendations, at 5.

<sup>64</sup> Id.

wetlands of all sizes in striking provisions that allow development of wetlands.<sup>65</sup> In Hood Canal, the Board rejected an exemption for even very small, truly isolated and poorly functioning wetlands where there was no evidence of the likely number of exempt wetlands, or of the potential cumulative impacts to those wetlands, adaptive management, or monitoring to assure no net loss.<sup>66</sup> Similarly, in Larson Beach Neighbors v. Stevens County, the Board held that exemptions for certain wetland sizes did not comply with the GMA in the absence of BAS showing that such actions would protect their functions and values.<sup>67</sup> And in Pilchuck, the Board held that the structure, value, and functions of CAs are inviolate and that a county's discretion to craft regulations that might result in some localized impacts or even loss should be "wielded sparingly and carefully for good cause" and that no circumstances would allow "the net loss of the structure, value and functions of such natural systems within a watershed or other functional catchment area."<sup>68</sup>

The exemption to develop smaller wetlands also conflicts with the BAS. The development of smaller wetlands would impact each of the four basic functions and values they perform: (1) water purification;<sup>69</sup> (2) maintenance of hydrologic functions and soil stability;<sup>70</sup> (3) providing habitat;<sup>71</sup> and (4) landscape beautification. Development adversely impacts these functions by altering hydrology with impervious surfaces, removing vegetation, constructing ponds, grading, and disturbing soil. Wetlands also can lose their capacity to filter pollutants once overloaded.<sup>72</sup>

The BAS strongly supports protecting wetlands of all sizes, and emphasizes the importance of smaller wetlands. Ecology's wetlands guidance states that "[t]he scientific literature does not support exempting wetlands that are below a certain size."<sup>73</sup> Earlier Ecology literature noted that "the loss of small wetlands is one of the most common cumulative impacts on wetlands and wildlife in Washington."

<sup>73</sup> ECY Guidance, at 8.

The exception for developing smaller wetlands must be removed, particularly in the absence of any understanding of the amount of impacts it would cause.

#### **5. Alterations to critical areas broadly authorized.**

As explained above, alterations of wetlands do not protect their functions and values and conflict with the BAS. Consequently, the City must remove its broad authorization to permit development activities that result in alteration of Category II, III, or IV wetlands at Section 19.70.230.B. on page 39 of the 3rd draft. This is particularly critical given the need to apply a precautionary approach for such a complex ecosystem as a wetland and in light of the substantially likely failure of efforts to compensate for functions lost to development.

Likewise, language about altering FWHCAs should be revised to clarify that alterations are allowed only as identified in the critical areas ordinance. As written, the text on page 60 (Section 19.70.325.A.) states that, “FWHCA’s or their buffers may be altered only if the proposed alteration of the habitat or the mitigation proposed does not degrade the functions and values of the habitat.” That language should be revised as identified in the table at Section A above to clarify that only those alterations specified elsewhere in the ordinance are authorized.

#### **6. Exceptions for activities in critical areas or buffers.**

The 3rd Draft proposes to allow a significant amount of development in critical areas or their buffers through exemptions at Table 19.70.040(A) and (B) or permitted alterations at Table 19.70.045. The following bullets identify some of these exemptions and recommend revisions (the page numbers refer to the page in the electronic document):

- (page 12) -- Passive Outdoor Activities. City staff testified to the Anacortes Hearing Examiner during an appeal of the SEPA review of the CAO that the City had removed the reference to cycling as a passive outdoor activity. However, in conflict with that testimony, the City has proposed to expressly identify biking as a passive outdoor activity. This reference should be removed.
- (page 13) -- the 3rd Draft removes "non-motorized" before trails in the exemption for maintenance, operation, repair, modification, or replacement of recreation areas in critical areas and buffers. Because motorized equipment typically causes more impact in critical areas and buffers, this exemption should apply to only non-motorized trails and facilities and that term should be reinserted into the ordinance.
- (page 14) – the 3rd Draft adds a new provision that allows for new trails to be developed in critical areas and buffers if an existing trail is already located in that critical area or

buffer. Particularly in the absence of a provision requiring the restoration of an existing trail in the event of construction of a new trail, this provision should be removed because it does not protect the functions and values of critical areas by doubling the amount of trail in that critical area or buffer. The old trail would otherwise continue to have impacts unless it were fully restored, and the new trail would add new impacts.

- (page 18) – Although the Public Services permitted alteration has been renamed the "Public Roads and Utilities" permitted alteration, it continues to allow development of critical areas and buffers for new transportation facilities, which according to City documents includes the Guemes Channel Trail. The text should be revised as identified in the table at Section A above to clarify that it applies to only automobile roads and not to other forms of transportation, as suggested by the change to the title.

- (pages 20-21) -- the 3rd draft includes a new provision that expressly allows new development in critical areas within the Anacortes Community Forest Lands ("ACFL"). This provision must be removed to ensure that the wetlands and FWHCAs in the ACFL are not impacted. To the extent that the purpose of this text is to allow some recreational development in portions of the ACFL that do not qualify as wetland or FWHCA, then the language could be revised to ensure that the CAO does not provide blanket approval to develop wetlands and streams in the ACFL.

## **7. Final Points.**

The following bullets identify several other necessary clarifications for the CAO (the page numbers refer to the page in the electronic document):

- (page 8) -- in the Project Evaluation section, 19.70.030, consistent with what has become the standard approach, the City should indicate that they may seek independent review of a project's impacts through a consultant funded by the applicant.

- (page 9) – Section 19.70.035.C.4. allows a complete rebuild of nonconforming structures damaged by fire/etc. To better implement the City's land use planning goals and for consistency with modern approaches and for fairness to other property owners, the text should be revised to clarify that if a building is destroyed more than 75% of its value, a rebuild will be consistent with current rules.

- (page 16) – On its face, Section 19.70.045.A. appears to broadly allow alterations to critical areas and their buffers. We recommend that the language be revised per the table at Section A above to ensure that it does not authorize unintended development in critical areas and buffers.

- (page 37) – The ordinance deletes the Ship Harbor wetland, Cannery Pond, and wetlands within the watersheds of Little Cranberry Lake, Whistle Lake, and Heart Lake from categorization as regionally significant wetlands. While we appreciate that these areas have been designated as Fish and Wildlife Habitat Conservation Areas, they continue to receive strong support for designation as regionally significant wetlands and should remain so designated.

- (pages 46 and 64) – Setbacks are intended to prevent buffer development or alteration. Yet the decks, roofs, overhangs, and stairways and steps that Sections 19.70.235.H and 19.70.330.D authorize would encourage the removal of buffer vegetation to avoid frequent maintenance of those areas from limbs or litter fall. Therefore, those items should be precluded in setbacks and that text removed. In addition, there is no scientific rationale for reducing the setbacks, and the provision for doing so should be removed.

- (page 57. **Stream names**) – the 3rd draft of the CAO would eliminate the CAO's existing reference by name to fifteen local streams. Evergreen asks that you reinstate those stream names as shown in the table above. In addition to honoring important community spaces, this action will demonstrate that the City has not unintentionally dedesignated those places currently designated as FWHCAs.

- (page 61) – Section 19.70.325.F. authorizes access roads through FWHCAs and buffers for subdivisions if a consultant reports that no other feasible alternative exists and impacts will be mitigated. Since new subdivisions will be able to design parcels to avoid the need for developing access roads in FWHCAs, that language should be revised to ensure that only subdivisions established prior to the critical areas ordinance update can take advantage of that exception.

Thank you for your consideration of these comments. We urge you to protect the functions and values of critical areas and to include the Best Available Science in doing so.

Sincerely,

Kyle A. Loring  
Attorney for Evergreen Islands

MARK S. FONSECA

*National Marine Fisheries Service, National Oceanic and Atmospheric Administration, Beaufort Laboratory, Beaufort, North Carolina 28516 USA*

**Abstract.** This study was undertaken to review the current status of permit-linked mitigation policies and practices in order to determine implications of the continued use of mitigation as a wetlands management tool within the United States. Based on reviews of both published literature and agency reports, our survey of past mitigation projects nationwide indicates that the success rate of permit-linked mitigation projects remains low overall. In addition, there is continuing difficulty in translating mitigation concepts into legal principles, regulatory standards, and permit conditions that are scientifically defensible and sound. Based on the record of past poor performance, we assert that continued piecemeal revision efforts focused on technical or scientific details are not likely to make compensatory mitigation more effective. There is need to acknowledge the extent to which non-scientific, real-world complications plague current policies and practices. To prevent continued loss of wetlands under compensatory mitigation, decisive action must be taken by placing emphasis on improving compliance, generating desired acreages, and maintaining a true baseline. Without selective changes in the status quo, current policies and poor implementation are likely to lead to further wetland losses.

**Key words:** *compensatory mitigation; habitat mitigation; habitat replacement; man-made wetlands; mitigation failures; mitigation policies; permit compliance; restoration of aquatic ecosystems; wetlands management; wetlands mitigation; wetlands restoration.*

*It's deja vu all over again.*  
(attributed to Yogi Berra)

### INTRODUCTION

In the space of two decades, mitigation has evolved from a seldom-used dictionary term to a heavily applied wetlands management practice that has become firmly entrenched with agency managers who are charged with the dual responsibilities of safeguarding the nation's wetlands and approving proposals for development. Questions about the advisability and success of mitigation projects surfaced over a decade ago (Race and Christie 1982), and persist in lively debates that continue to the present, bolstered by expanded scientific research and increased practical experience (e.g., Race 1985, Harvey and Josselyn 1986, Race 1986, Batha and Pendleton 1987, Zedler 1987, O'Donnell 1988, Redmond 1992). At the heart of the current debate is the practice of permit-linked compensatory mitigation: required actions that are intended to compensate for environmental damage or loss of habitat through replacement of functions, values, or acreage of wetlands proposed for destruction. Very often compensatory mitigation involves creation of new wetlands or enhancement of existing wetlands.

According to current federal policy, explicit trades

between permitted impacts and mitigation requirements should not be allowed, and mitigation efforts should be "sequenced," with a preference for avoiding and minimizing wetland impacts before resorting to compensatory mitigation. However, with so much at stake in the permit process, the unfortunate reality is that discussions often focus heavily on compensatory mitigation as a means of offsetting habitat damage or loss. Although hardly responsible for the majority of national wetland losses, the practice of compensatory mitigation remains a serious concern because it is a bartering scheme that trades permission to damage a known quantity of wetland area for the promise of some kind of replacement, sometimes at locations away from the impacted area. The manner in which this bartering is pursued varies widely under local, state, and federal agencies whose jurisdictions overlap in wetlands. Thus, the process of planning and permitting compensatory mitigation projects is not at all consistent.

In this paper we take a renewed look at mitigation in a broad context and ask once again whether mitigation—as currently conceived in policy and applied in practice—is a useful wetlands management tool or, rather, an option that inevitably contributes to further incremental loss of habitats regionally and nationally in response to persistent demands for development permits.

<sup>1</sup> Manuscript received 14 July 1994; revised 3 March 1995; accepted 8 March 1995.

<sup>2</sup> For reprints of this group of papers on wetland mitigation, see footnote 2, page 33.

## BACKGROUND

In reviewing the literature, it became clear we can add little that has not already been said in the mitigation debate. Every year, there are conferences in the United States with mitigation or restoration as a theme (e.g., Annual Symposium on the Restoration and Creation of Wetlands, Hillsborough Community College, Tampa, Florida). Moreover, several texts have addressed the full spectrum of mitigation issues (Kusler and Kentula 1990, NRC 1992, Thayer 1992). Each volume provides summaries of definitions, analyses of scientific advances, and discussion of protocols and guidelines for a variety of wetland mitigation, restoration, and creation options. It is clear that the field has progressed considerably since a time when there "was no consistent definition of what [mitigation] was nor any consensus as to how it should be applied" (Race and Christie 1982).

While the proliferation of studies about mitigation is both encouraging and helpful, it is interesting to note that much of the work on mitigation remains outside the peer-reviewed literature. A computer search using BIOSIS revealed only 44 citations since 1987 for mitigation when the word was combined with the terms habitat, or wetland, or ecosystem. In addition, many of these entries were abstracts. In our opinion, this lack of peer review represents a serious flaw in the evolution of mitigation technology and philosophy.

If there is so much scientific and practical information about mitigation, why is there a lingering undercurrent of doubt about compensatory mitigation (Roberts 1993)? Part of the reason may come from its continuing close association with, and reliance on, restoration ecology. The National Academy of Sciences report on aquatic ecosystem restoration (NRC 1992) emphasizes the tremendous potential of restoration techniques for replicating lost functions and values as well as former plant and animal communities. In fact, the report advocates a goal of "restoring 10 million wetland acres" ( $4.05 \times 10^6$  ha) over the next 18 yr throughout the nation. However, as noted by Nicholas (1992):

*one of the report's major contributions is an honest picture of the present state of wetland restoration—rudimentary, at best; criminally inept, at worst. The lack of knowledge about wetland functions and values and the lack of a larger planning context in which restorations are carried out are identified as serious limitations in ongoing efforts.*

According to the NRC (1992) report, mitigation efforts cannot yet claim to have duplicated lost wetland functional values; nor has it been shown that restored wetlands maintain regional biodiversity or recreate functional ecosystems.

Further doubts about compensatory mitigation are raised from reviewing the outcome of actual mitigation

projects in the field. Despite evolving sophistication by the research and management community, the results are not encouraging, and the success of mitigation remains in serious doubt.

## SURVEYS OF MITIGATION PROJECTS

Race (1985) contended that premature extrapolation of experimental results led to institutionalization of mitigation as a policy with little to suggest that it fulfilled expectations of restored ecosystem function. She based this conclusion on a review of 6 yr of permit history and surveys of 33 restoration projects located in San Francisco Bay. In general, noncompliance with permit conditions was the norm. Unfortunately, these findings were not unique.

Eliot (1985) reviewed 58 mitigation projects in San Francisco Bay that had been permitted over a 6-yr period. She found they did not adhere to established mitigation policies, they were frequently unsuccessful, and almost half of the projects had not been accomplished by the specified permit completion date. She advocated effective enforcement as the key to mitigation project completion, noting that its absence accounted for much of the noncompliance among permits in her study. She also noted that mitigation ratios (ratio of habitat replaced to habitat lost) varied widely among projects and were not consistently used to determine the acreage of compensating projects. This kind of arbitrariness all but guarantees opposition and legal challenges from developers, who generally feel that current wetlands policies are unfair and inequitable anyway (Wilmar 1986, Wilms 1990).

Quammen (1986a) reviewed studies of mitigation projects in various parts of the country, including Virginia, New England, New Jersey, Florida, and San Francisco Bay. She concluded that on the whole:

*compliance with permit conditions is low and that effectiveness of restoration to compensate for wetland losses cannot yet be determined. Only when the project objectives and design criteria are clearly stated as part of the permit conditions, and monitoring is conducted and reported, will we be able to evaluate whether created wetlands are able to compensate for the losses in natural wetlands.*

A New Jersey field survey and qualitative evaluation of 30 artificial salt-marsh projects (wetland permit and violation cases) revealed an array of problems including wave damage, sedimentation problems, deteriorating bulkheads, and unplanned shifts in species composition (Shisler and Charette 1986). Additional detailed quantitative sampling at eight of the sites indicated significant differences in nearly all sediment characteristics, vegetational parameters, and macroinvertebrate measures when compared to adjacent natural marshes. The authors concluded that the "restoration and creation of artificial marshes is in an early state of development . . . and their long-term success under var-

ious environmental conditions still needs to be experimentally tested.”

R. A. Cobb<sup>3</sup> conducted surveys of a wide variety of wetland mitigation sites in Texas and concluded that permitted activities led to a 0.6:1 ratio of habitat replacement to loss. He concluded that conflicting goals among agencies, lack of customized plans, lack of performance bonds, inexperience, and absence of a structure to assure long-term accountability for the maintenance of a site all conspired to produce meager results.

A report by the Staff of the Bay Conservation and Development Commission (BCDC 1988) evaluated the success of 14 permit-associated mitigation programs involving tideland restoration in San Francisco Bay. They reported that “mitigation programs can and, in most cases where work has been adequately performed, have successfully created and enhanced Bay resources.” However, their criteria for success were based on whether a completed project met the permit’s specific mitigation requirements, rather than how well it replaced or offset the specific, adverse Bay-related impacts of that project (compliance vs. functional success as described by Quammen 1986b). They noted (BCDC 1988) that “while many of the mitigation projects were successful, some well-designed projects have yet to create the desired resources,” suggesting the need for mitigation areas “that are larger in size and greater in resource value than the area disturbed by the . . . project.” Five of the 14 projects experienced some delay in completing all or a portion of their mitigation requirements as a direct result of being unable to either find and/or acquire a suitable restoration site. The report recommended a number of ways to increase overall success including increased attention to enforcing mitigation requirements, greater specificity in prescribed mitigation plans, and requiring that mitigation work begin prior to undertaking the actual permitted project.

In a comprehensive Florida study, the Florida Department of Environmental Regulation (FDER) revisited 119 habitat-creation, enhancement, or preservation sites covered under 63 permits (*unpublished report* submitted to Governor L. Chiles [5 March 1991]).<sup>4</sup> The survey found that only 6% of the permits were in full compliance, and that in 34% of the permits no mitigation had even been attempted—although losses of natural habitat had gone forward. Interestingly, permits for tidal areas fared better than freshwater sites, with 27% vs. 12% “ecological effectiveness.” To counter these losses, the report suggested that more staff, greater upfront mitigation, filing-fee assessments, and administrative fines for noncompliance were needed to counter habitat losses.

Lewis (1992) combined the FDER study findings with data from two other Florida studies of mitigation projects (D. W. Crewz, *unpublished report* [Mid-project, 1990];<sup>5</sup> K. L. Erwin, *unpublished report* [1991]<sup>6</sup>) and reported: “Taken as a whole, these three studies looked at 174 regulatory agency-permitted mitigation projects and concluded that only eight achieved compliance with all permit requirements. That’s only a 4.6% success rate . . .”

A detailed audit by the Florida Department of Environmental Regulation reviewed the specifics of >1300 permits, representing ≈10% of all dredge-and-fill mitigation permits during a 5-yr period (FDER, *unpublished report* [1991; Audit Report number AR-249]) (see footnote 4). Their reviews included subsamples of permit files and compliance records as well as inspection of actual mitigation sites and interviews with applicable personnel. The audit reported inadequate record keeping and poor tracking of wetlands mitigation data, a high rate of noncompliance with permit conditions by permittees, inconsistencies in permit conditions within and among Department offices, and inadequate inspections and enforcement. For example, the audit found that 43% of the mitigated permits did not have conditions considered to be adequate and readily enforceable. Only 39% of the permittees had fully complied with the permit conditions in the required time; many projects had not even been started, while others were found to be in noncompliance for reasons including improper elevations, incorrect amounts or types of vegetation, inadequate monitoring or maintenance, and inadequate size or configuration. Only 8% of the freshwater sites and none of the tidal sites were evaluated as being *ecologically* successful, and 28% were so unsuccessful that major remedial action was recommended. The auditors concluded that “the wetlands mitigation program has generally been ineffective,” and that despite some recent improvements, many problems remain.

Mager (1990) documented the existence of at least 763 permitted projects and echoed concern about the lopsided, upfront attention given to mitigation proposals as compared to follow-up: “There is virtually no follow-up once a permit is issued and the ultimate fate of thousands of acres of wetlands is unknown.” These concerns are especially serious when one considers national trends. As noted by Zedler (1996a), a U.S. Environmental Protection Agency (EPA) review of permit records for eight states over the past two decades documented 724 permits in the cumulative record, with 898 wetlands impacted and 745 compensatory wetlands required.

The serious shortcomings of mitigative activities

<sup>3</sup> *Unpublished report* (1987) to U.S. Fish and Wildlife Service, Corpus Christie, Texas, USA.

have also been expressed by others (Newman 1986). Recently, the Committee on Restoration of Aquatic Ecosystems advised against the use of wetland restoration to offset or justify the destruction of other wetlands until wetland restoration science has moved from a trial-and-error process to a more predictive science (NRC 1992). Subsequently, a review article in *Science* noted the sober reality that under present mitigation policies and practices "losses are likely to be uncompensated for and that what we call mitigation has a high chance of failure" (Roberts 1993). Experts interviewed for that article expressed the consensus that "compensatory mitigation should be the last resort, and must be based on the best available science, with strict, agreed-upon standards to judge success, perhaps by a government agency or private groups, and a commitment by developers to make mid-courses corrections when needed—what Zedler calls 'adaptive management' of the ecosystem." Furthermore, the article concludes with the suggestion that regulatory agencies should require, whenever feasible, that the replacement wetland be completed up front, before the natural one is destroyed.

#### DISCUSSION

Based on over a decade of survey results, the cumulative record of past mitigation projects remains undeniably poor overall, with disappointingly few examples of success. With hindsight, there are undoubtedly many persuasive explanations for poor performances or partial successes—including inadequate design, poor hydrology, improper location, wrong contours, incorrect elevation, small size, poor sediment characteristics, lack of skill by constructors, invasion of exotic species, exposure to severe storms, vagaries of nature, or surveys performed too early in the developmental stage to demonstrate success. It is not our intention to reanalyze past projects with the goal of identifying and systematically ranking the reasons for poor performance. In our opinion, such a task would be both unnecessarily costly and unproductive. Rather, it is time to admit the limitations in both our knowledge and our ability to gain additional information in a timely fashion. As discussed by Ludwig (1993), there comes a time when it is advisable to seek resolution to resource management issues outside the traditional scientific realm. While there is certainly need for continued scientific and on-site research, it is *doubtful whether additional scientific information will be sufficient to resolve the current problems of compensatory mitigation* or make it more effective. In the face of escalating political attacks on wetlands protection efforts and the apparent necessity of continuing to use mitigation as a wetlands management tool, it is arguably more important to explore ways to improve overall mitigative performance as soon as possible. It is also important to acknowledge a number of real-world com-

plications that are likely to frustrate attempts to improve compensatory mitigation policies and practices.

#### *Tensions between a landscape approach and existing permit policies*

Over the years the conceptual view of environmental impacts has evolved significantly, from an early perspective that assessed mainly direct project impacts, to a later view that focused on cumulative impacts, and most recently to a landscape approach. This evolution in perspective has not been accompanied by corresponding shifts in the wetlands permit process. For example, there is considerable debate about the correct scale over which to evaluate wetland functions and impacts to them. Bedford and Preston (1988) and Zedler (1996b) argue persuasively that the inability to document cumulative impacts has resulted in a continued focus on impacts bounded by the arbitrary definitions of a given project, without proper consideration of the linkages between communities and ecosystems. This disparity between landscape planning goals and individual projects often conflicts with individual property rights, thereby setting severe limits on the use of landscape approaches with compensatory mitigation.

The problem is largely a social one; we are a society that has not progressed past the frontier economics that initially categorized wetlands as a resource to be reclaimed, and that emphasizes private-sector goals over public concerns (M. E. Colby, *unpublished report*).<sup>7</sup> How, in the absence of strict environmental oversight, can a landscape approach be utilized in compensatory mitigation? Barring significant erosion of private property rights, we submit that it cannot. Depending on the scale chosen, landscape management may encompass literally thousands or millions of individual property owners. Taking a large-scale, ecosystem approach to wetlands management is a significant change in natural resource management policies, one representing a major paradigm shift that will require radical revision in values, management practices, and institutional structures in order to succeed (Cortner and Moote 1994).

Maintaining consistency in the permit process is critical if we wish to avoid problems caused by conflicts with private ownership and questions over legal "taking" of land or inequitable government compensation for land in question. Thus, integrating ecologically relevant concepts such as landscape-scale decision criteria need more than good science; it will also require conscious redesign of the entire permitting infrastructure to avoid legal challenges. If developers are not offered what they perceive as rational alternatives, we should not be surprised to see them respond by litigating against compensatory mitigation (Wilmar 1986).

<sup>7</sup> Policy planning and research working paper series, publication number WPS 313. Available from Strategic Planning and Review Department, The World Bank, New York, New York, USA.

Currently, review of mitigation requests is on a case-by-case basis (and will likely remain so for a long time), a process that explicitly recognizes private ownership of land and presumably treats all projects with the same set of guidelines or requirements. Adopting a landscape approach to compensatory mitigation may generate unanticipated legal complications. For example, later permittees might face more stringent controls or requirements because of cumulative impacts to the regional ecosystem caused, in part, by earlier permittees. For the landscape approach to guide compensatory mitigation projects, there must be an acceptable mechanism to justify changes in permitting criteria while balancing individual property rights. The practice of adaptive management—utilizing post-approval monitoring, changes in performance standards, revisions of compliance criteria, and repeated corrective measures—could result in charges of inconsistency or capriciousness if regulators repeatedly change the rules and requirements for permit holders.

*Exemptions, small cumulative losses, and continued erosion of the wetlands baseline*

Gladwin and Roelle (1992) noted that exemptions under the Corps of Engineers Nationwide Permit 26 program (authorizing discharges in “<10 acres” (4.1 ha) of wetlands)<sup>8</sup> cause significant unrecorded wetlands losses from many small impacts. The current structure of permit and exemption processes virtually guarantees incremental, cumulative loss of wetlands. This means that failed mitigation projects or other small losses will not be detectable until their cumulative impact is seen on a very large scale. When detectable, these cumulative losses would indicate an alarming state of decline where remedial action is bound to be prohibitively expensive.

In some quarters there is optimism that remote-sensing technology can be brought to bear upon cumulative impact problems and landscape-scale wetlands management. In order to guide compensatory mitigation planning, the resolution of the landscape assessments must be consistent with the physical size of the compensatory mitigation projects. Rivera et al. (1992) determined that, depending on the sensing technology, 36–68% of the projects being approved for wetland alterations occurred below the detection limit of the technologies at hand. Although new technologies can provide resolution at <1-m scales, such as those being used in San Diego Bay (J. Zedler, *personal communication*), it may be some time before these are used nationwide. The sheer mass of data that would be processed for watershed-scale maps with 1-m resolution

seems sufficiently costly at present to inhibit regional planning processes. Further, expecting routine high-resolution mapping of individual mitigation projects seems unrealistic given the widespread lack of follow-up and monitoring. At least for the foreseeable future, remote sensing will probably not provide oversight data for small mitigation projects nor aid in quantitative assessment of their cumulative impacts. Without accurate information on acreages of historical and current losses, it is difficult to address questions such as “what is the baseline level of habitat?” and “to what standard do we compare the extant acreage?”.

Many resource managers argue that mitigation is better than getting nothing at all in return for coastal development projects that would otherwise proceed with no recompense for environmental degradation. We disagree. In the short term, mitigation projects that do not meet the no-net-loss criteria become a liability in the effort to sustain local ecosystem functions. Over the long run, wetland management policies that allow development before the delivery of prescribed mitigative compensation contribute to the downward spiral of cumulative habitat loss. These losses may have to be offset by other projects that must provide higher ratios of replacement acreage to lost acreage for compensation. Without overcompensation through other projects, the “better something than nothing” approach constitutes a tacit approval of accepting net loss of habitat.

#### RECOMMENDATIONS

As described above, vexing problems continue to plague the policies and practices of compensatory mitigation. There is great difficulty in translating mitigation concepts into legal principles, regulatory standards, and permit conditions that are scientifically defensible and fair. Despite the dedicated efforts of researchers, practitioners, and regulatory officials nationwide over the past decade, there remains no universally accepted standard for required compensation—a situation that, in our opinion, is likely to persist for some time, even in the face of expanding research in restoration ecology.

While we agree there are many ways to reduce the risks of failure in wetlands restoration projects (e.g., NRC 1992: Chapter 6), it is important not to be overly optimistic that either more research, more time, more highly trained consultants, or more money will necessarily mean reduced failure rates. Even when wetland restoration experts have adequate budgets, ample time, extensive on-site experimental data, and the ability to take an adaptive management approach, functional success cannot be guaranteed (Zedler 1996b).

The permit process is still significantly ahead of the scientific debate regarding issues such as functional equivalency, biological diversity, and reconstruction of landscape patterns. Questions about substitute wetlands will no doubt continue even as additional permits are issued. Until we begin to approach at least rudimentary

<sup>8</sup> The Clean Water Act (1972) authorized the Corps of Engineers to issue permits for discharges of dredge or fill materials in the waters of the U.S. Also, the Corps was given additional permit authority in 1984 under the Nationwide Permit 26 Program (NWP 26) which allows fill of <10 acres in non-tidal wetlands.

compliance on a regular basis (such as actually initiating the work), no one will be able to determine whether these habitat exchanges can be justified on scientific grounds. Getting to compliance is the key. There is ample reason to believe that compensatory mitigation can still work—but only if we act decisively to implement some of the many insightful recommendations that have already been put forth in the literature.

#### *Activities aimed at improving compliance*

A stronger emphasis on permit compliance and enforcement is needed to improve the overall success rate of mitigation projects (Redmond 1992). Up-front completion of mitigation projects will help the situation, but only if there is some way to monitor, verify, and enforce actual compliance *prior* to commencement of the development project. Even if compliance levels eventually approach 100%, we must continue to monitor and evaluate functional equivalency of the mitigated habitat vs. the natural area that it replaces.

As noted by Lewis (1992), mitigation programs currently lack the tools necessary to enforce and ensure success of wetlands creation and restoration projects or even to see that they get done. Several factors combine to deter agencies from vigorous enforcement including the actual dollar costs of enforcement, the political costs of added staff, and the political costs of prohibiting development (Jensen 1987). Despite these problems, agencies must reconsider the issue of enforcement and monitoring, exploring ways to increase effective oversight of mitigation projects and ensure their compliance with permit conditions. Unless enforcement and monitoring are emphasized, noncompliance will likely continue as the norm, because there are no penalties or incentives for a permit holder to adhere to permit conditions.

In seeking to address the problems of noncompliance and lack of enforcement, there is need to plan carefully and avoid pitfalls associated with proposed solutions. For example, Wold (1990) described the problem caused by disparity of fine assessments for NOAA's [National Oceanic and Atmospheric Administration] civil penalty policy for overfishing. He concluded that the fines were so low in contrast to the benefits of overexploiting the resource as to not be a deterrent, and that inconsistent application of fines led to litigation because of perceived unfairness. Proposed penalties or incentives that seek to improve compliance must be considered in light of the beneficial services of functional wetlands (e.g., erosion control, primary and secondary production, aesthetics, etc.). With wetlands, various approaches that either penalize or provide incentive to a permit holder can be found, including performance bonds, civil fines and penalties, mitigation banking, and in lieu fees. Because none of these approaches, especially mitigation banking, is without problems (King 1992, Lewis 1992, King and Bohlen 1994), resource managers should review how

these alternatives contribute to overall compliance and no-net-loss-of-wetlands goals.

We strongly advocate that restoration and/or mitigation be *on site* and *in kind* as it has the greatest potential to minimize disruption of remaining ecological functions (by recognizing the importance of position in the landscape as opposed to simply quantities of habitat). This tactic should be especially emphasized in areas where significant ecological linkages and functions still exist. However, in highly disturbed settings such as urbanized areas where substantial habitat fragmentation has already occurred and ecological functions may be further impaired by the very act of mitigation (e.g., mobilization of hazardous materials during recontouring), alternatives such as mitigation banks may be a more realistic solution, albeit not without problems. Clinging to a landscape perspective in extremely fragmented or polluted settings makes little ecological sense in locations where the landscape has essentially vanished. Whatever actions are taken to increase compliance with permit conditions, they must truly lead to effective prohibition of wetlands degradation.

Clearly, alternative approaches must be executable in the face of tight budgets and conflicting agency mandates. One suggestion to improve compliance might be implementation of an approach similar to that used by the U.S. Internal Revenue Service (the tax-collection branch of the U.S. federal government), with audits, fines, and civil penalties. Such an approach may be tractable for agencies, both politically and economically. The idea is not to survey every permitted project after the fact, but to randomly choose projects and hold them to the strict criteria put forth in the permit conditions. The uncertainty of such an *audit* may well provoke much-needed attention to detail in mitigation projects. In addition, any fines that were generated for noncompliance could be used for actual habitat restoration purposes if they are so earmarked. By establishing expectations of audits for performance and compliance, repeated mistakes by unqualified practitioners would eventually be discouraged.

#### *Budget reallocations*

We recognize that any recommendation to increase monitoring, enforcement, and compliance-related activities will necessarily require a reexamination of how agency dollars are allocated. In general, agency dollars have been divided among tasks such as damage assessment; permit reviews and negotiations; inventory and resource surveys; research and development; and, to a lesser extent, enforcement and compliance. Assuming that increased funding will not be available, it may be necessary and advisable to reallocate funding in ways that emphasize permit compliance, even if this means de-emphasizing some research and inventory tasks, especially coarse-scale, dated inventories.

*Focus on generated acreage and establish  
a true baseline of acreage*

Many researchers have commented on the lack of information comparing important biological functions of human-made and natural wetlands. However, in our view, concerns about function are eclipsed by concerns about generating habitat in the first place. The main priority should be on actually generating the acreage of habitat for which permits have been written. Once acreage is assured, only then does it make sense to emphasize the debate over how to measure wetland quality, function, natural equivalency, or persistence. If required acreage is not being delivered on a regular basis, then permit conditions must be strengthened.

*Conclusions*

As we noted at the outset, the issues in the debate over mitigation are not new, and neither are our recommendations. In fact, much of what we have discussed echoes the collective wisdom of researchers, practitioners, and agency managers, who for years have been making individual recommendations about their particular situations. The time has come to act deliberately on these collected recommendations with the aim of improving overall mitigation success. Certainly, this means applying technical skills and scientific knowledge; but it also requires an appreciation of the socio-political context of that work.

In this spirit, we suggest the need to plan strategically and prioritize actions selectively in order to realize a true no-net-loss of wetlands. We must avoid continued piecemeal revision efforts focused on technical or scientific details that are not likely to make compensatory mitigation a more effective management tool. The time has come to refocus compensatory mitigation efforts in a way that acknowledges underlying problems linked with unavoidable cultural, political, development, economic, and institutional constraints. This in no way undermines the importance of scientists or restorationists in the process; everyone must take a larger view of the mitigation process, translating and implementing their findings where appropriate. But to prevent continued losses of wetlands under compensatory mitigation, we must reorder our priorities, putting emphasis on improving compliance, generating desired acreage, and maintaining a true baseline. Unless we change the status quo of compensatory mitigation, we fear that the baseline of wetlands acreage will continue to erode in the face of faulty policies and poor implementation. We think the system is fixable, but only with deliberate, selective changes. In our optimistic moments we look forward to a time when review papers like this are not a decadal event.

ACKNOWLEDGMENTS

The authors extend special thanks to Joy Zedler for her many helpful suggestions and extreme patience during the preparation of this manuscript. Thanks also to two reviewers,

## Abstract

Wetlands are among the most productive and economically valuable ecosystems in the world. However, because of human activities, over half of the wetland ecosystems existing in North America, Europe, Australia, and China in the early 20th century have been lost. Ecological restoration to recover critical ecosystem services has been widely attempted, but the degree of actual recovery of ecosystem functioning and structure from these efforts remains uncertain. Our results from a meta-analysis of 621 wetland sites from throughout the world show that even a century after restoration efforts, biological structure (driven mostly by plant assemblages), and biogeochemical functioning (driven primarily by the storage of carbon in wetland soils), remained on average 26% and 23% lower, respectively, than in reference sites. Either recovery has been very slow, or postdisturbance systems have moved towards alternative states that differ from reference conditions. We also found significant effects of environmental settings on the rate and degree of recovery. Large wetland areas (>100 ha) and wetlands restored in warm (temperate and tropical) climates recovered more rapidly than smaller wetlands and wetlands restored in cold climates. Also, wetlands experiencing more (riverine and tidal) hydrologic exchange recovered more rapidly than depressionnal wetlands. Restoration performance is limited: current restoration practice fails to recover original levels of wetland ecosystem functions, even after many decades. If restoration as currently practiced is used to justify further degradation, global loss of wetland ecosystem function and structure will spread.

## Introduction

From tropical mangroves to boreal peatlands, wetlands are amongst the most productive and economically valuable ecosystems in the world [1]. They provide critical ecosystem goods and services, including carbon storage, biodiversity conservation, fish production, fuel production, water purification, flood and shoreline surge protection and erosion control, and recreation [1–3]. However, owing to human activities, over half of the wetland ecosystems existing in the early 20th century have been lost in North America, Europe, Australia, and China [2]. Over the last century, restoration of degraded wetlands and creation of new ones have been attempted, in efforts to recover physical, chemical, and biological processes and entities lost because of wetland destruction or degradation [4]. Frequently, however, this approach does not restore ecosystem structure and functions to preimpact levels [5–8]. In North America (including Canada, United States, and Mexico) alone, over US\$70 billion have been spent attempting to restore more than 3,000,000 ha of wetlands in the last 20 y (see Text S1) [9], but the recovery trajectories of structure and functions in restored wetlands have not yet been globally assessed [10,11].

After degradation or natural perturbation, ecosystem structure and functions recover towards reference levels [7,12], but recovery

rates might be affected by the physical characteristics of the ecosystem, the degrading activity, or the environmental setting [7,12]. Abiotic factors, such as size of restored ecosystems and climate, might affect recovery rates. It could be expected that intensely engineered small (few hectares) wetlands might recover faster than less manipulated, large wetlands (hundreds of hectares) to their original characteristics, but this prediction remains unconfirmed. Higher recovery rates could also be expected in warmer climates than in cold ones, because of accelerated ecosystem processes [7,13]. Restoration efforts during the recovery process may lead ecosystems to reference states or redirect them towards alternative states [14–16] that could also be initiated by prerecovery disturbance itself. If recovery is slow, it could be difficult to distinguish between these alternatives. We surveyed long-term (up to 100 y, available for some but not all of the studied variables) chronosequences of restored wetland ecosystems from 621 restored and created wetlands relative to 556 reference wetlands (Figure S1). Following Article 1.1 of the Ramsar Convention of Wetlands [17], we considered wetlands to be marshes, peatlands, floodplains, mangroves, depressionnal wetlands, and lacustrine wetlands—submerged permanently or periodically under flowing or still fresh, salty, or brackish water. We compared structure and function of 401 wetlands restored on sites where they had been previously degraded and 220 newly

## Author Summary

Wetlands, which include tropical mangroves and boreal peatlands, are among the most valuable ecosystems in the world because they provide critical ecosystem goods and services, such as carbon storage, biodiversity conservation, fish production, water purification, and erosion control. As global change accelerates the loss of wetlands, attempts are increasing to restore this fragile habitat and its associated functioning. There has been no global evaluation, however, of how effective such restoration efforts have been. Here, we present a meta-analysis of the biological structure (driven mostly by plant communities) and biogeochemical functioning (driven primarily by the storage of carbon in wetland soils) of 621 wetland sites. Our analysis suggests that even a century after restoration efforts, these parameters remained on average 26% and 23% (respectively) lower in restored or created wetlands than in reference wetlands. Our results also indicate that ecosystem size and the environmental setting significantly affect the rate of recovery. Recovery may be more likely and more rapid if more than 100 contiguous hectares of habitat are restored. In warm climates, and in settings linked to riverine or tidal flows, recovery can also proceed more rapidly. In general, however, once disturbed, wetlands either recover very slowly or move towards alternative states that differ from reference conditions. Thus, current restoration practice and wetland mitigation policies will maintain and likely accelerate the global loss of wetland ecosystem functions.

created wetlands (wetland creation *de novo* is currently accepted for environmental mitigation [4]). We also examined how size of ecosystem and its environmental setting (climate regime and hydrologic connectivity) affected recovery. Using a standardized method (see Materials and Methods), we selected 124 studies (see Text S2) in which ecological responses were measured at known time intervals since restoration. From the selected studies, we extracted 1,501 data points (Tables 1, S1, and S2) comparing hydrologic, biological, and biogeochemical variables in restored or created and reference wetlands. Response ratios (see Materials and Methods) were calculated for each data point. Variables selected

from the same studies were not necessarily independent (see Materials and Methods), so statistical inferences must be interpreted cautiously.

We compared recovery trajectories of hydrologic, biological, and biogeochemical variables of restored and created wetlands to address three questions: (a) How fast are biological and biogeochemical components of restored ecosystems changing relative to less perturbed reference ecosystems?; (b) Do these changes trend towards or away from the predisturbed ecosystem or parallel control ecosystems?; and (c) Does wetland size or environmental setting (regional climate, hydrologic connectivity) affect recovery?

## Results/Discussion

### Hydrologic and Biological Recovery

Some hydrologic features can often be restored by manipulating local topography, soil permeability, surface and ground water flows—physical features that are usually engineered in wetland restoration projects. Hydrological features defined for these analyses (Table 1) appeared to be recovered immediately after restoration (Figure 1A), but see Cole [18], Hunt et al. [19], Ahn and Dee [20], and Kumar and Zhao [21] for deeper considerations of challenges to hydrologic restoration in wetlands (from factors like climate variation [20] or complex flow paths of water through heterogeneous vegetation and soils [21]). In addition, all hydrologic variables reported in studies we reviewed were followed only for 10 y to 15 y, so longer-term changes remain unknown.

In contrast to reported hydrologic performance, biological structure (as defined in Table 1) in restored or created wetlands, recovered to only 77% (on average) of reference values (Figure 1A and 1B; Table S3), even 100 y after restoration, when data on 14 taxa from two studies of three wetland sites are available [22,23]. Abundance, species richness, and diversity of native animals and plants in wetlands were severely reduced following degradation. After restoration, recovery proceeded at different rates, and trajectories plateaued at different levels. Vertebrate assemblages reached similar structural values to those in reference wetlands within 5 y (Figure 1B). Vertebrate richness recovered more slowly than abundance ( $p=0.021$ ; Figure 2A), possibly reflecting responses by a few highly mobile vertebrate species [24,25] once

**Table 1.** Variables measured simultaneously in restored or created and reference wetlands to estimate wetland restoration performance over time.

doi:10.1371/journal.pbio.1001247.t001

**Figure 1. Recovery trajectories of created and restored wetlands.** Chronosequences of the means ( $\pm$ standard error [SE]) of the response ratios (see Materials and Methods) of restored and created wetlands at successive age classes of 5 y or 10 consecutive y for hydrology, biological structure, and biogeochemical functions (A) and for the main biological structural components (B). Chronosequences of the means ( $\pm$ SE) of the element loss in soils of restored or created wetlands at successive age classes of 5 y or 10 consecutive y (C). The zero value dashed line represents reference wetlands. Only trend lines for those variables for which we had enough data points (see Materials and Methods) were plotted (N, number of data points used to calculate the mean [ $\pm$ SE] per age class; Y, years after restoration. Subscripts are as follows: bp, biogeochemical processes; bs, biological structure; C, carbon; hf, hydrological features; m, macroinvertebrates; N, nitrogen; p, plants; P, phosphorus; v, vertebrates). doi:10.1371/journal.pbio.1001247.g001

hydrological connectivity was restored. Macroinvertebrates (64% noninsects) took 5 y to 10 y to statistically converge with reference assemblages in restored and created wetlands (Figure 1B), and average values never reached absolute reference levels. Many macroinvertebrates cannot recolonize new or restored wetlands by themselves, but are carried in by flowing water or other organisms [26,27]; however, their short life cycles (often annual or semi-

annual) could accelerate population recovery after they arrive [28,29].

Plant assemblages in restored and created wetlands were slowest to recover. Plants took on average 30 y to converge statistically with reference states; although again, absolute average values of structural features of plant assemblages remained lower than reference levels even after 100 y following restoration (Figures 1B and 2B). The slow and incomplete recovery of plant assemblage might be due to dispersal limitation, vulnerable early life history stages, or sensitivity of any life stage to altered conditions (e.g., reduced organic content of soils, discussed below) during early succession following disturbance [30,31]. Other factors, such as exotic colonists, subsequent disturbance or altered disturbance regimes, priority effects (historical legacies), and nonlinear interactions may also lead to delayed recovery or persistent differences between restored biota and those in reference wetlands [6,31,32].

### Biogeochemical Recovery

Four biogeochemical responses were sufficiently well documented in some studies we reviewed to examine trends over time: these were the storage of carbon, nitrogen, and phosphorus (Figure 1C) (see also storage and cycling combined for carbon and nitrogen in Figure S2A), and the accumulation of organic matter in soil (Figure S2B). The storage and cycling of carbon and nitrogen were drastically reduced from preimpact levels after degradation. In contrast, phosphorus storage seemed unaffected. After restoration, responses were variable. Initially, carbon storage increased slightly but then plateaued below reference levels; nitrogen storage and cycling increased slowly but continuously; and phosphorus storage remained unaffected. Wetland degradation notoriously oxidizes stores of accumulated organic carbon and releases CO<sub>2</sub> to the atmosphere, as aerobic conditions accelerate microbial respiration [2,33]. After wetland hydrologic regimes are recovered, more anaerobic conditions allow stores of organic carbon to slowly reaccumulate in the soil. After 20 y, however, carbon storage in restored and created wetland soils was still significantly lower (by 50%;  $p = 0.008$ ) than in reference wetlands (Figure 1C; Table S3; Text S1; data from six studies of 21 wetlands) Organic matter accumulated slowly [34,35], so that average values remained only 62% of the value at the reference wetlands 20–30 y following restoration (Figure S2B; data from seven studies of 21 wetlands).

Aerobic conditions in degraded wetlands also perturb nitrogen storage and cycling, allowing mineralization of organic N and transformation of ammonium to nitrate [2]. Nitrate is quickly processed by microorganisms and plants, leaving the original pool of nitrogen in the soil depleted or unavailable. Nitrogen storage remained significantly lower in restored wetlands for 30 y after the wetlands were restored or created (Figure 1C; Table S3). Depleted or unavailable soil nitrogen can limit wetland productivity, retarding carbon storage [33,36]. In contrast, total phosphorus decreased only slightly in restored or created wetlands and did not show significant differences with reference wetlands (Figure 1C). Although, phosphorus chemical fractions could change in representation, the amount of total phosphorus did not change significantly [37]. This lack of variation in phosphorus might be explained because of the more conservative cycling by phosphorus (lack of exchange with the atmosphere) [38]. In addition, without extrinsic inputs, phosphorus levels would be geologically determined.

After 50 y to 100 y, restored wetlands recovered only to an average of 74% of their biogeochemical functioning relative to reference wetlands (Figure 1A; data from two studies of seven wetlands; data of wetlands recovering for more than 50 y after

**Figure 2. Recovery trajectories of animal and plant richness and density.** Chronosequences of the means ( $\pm$ standard error [SE]) of the response ratios (see Materials and Methods) of restored or created wetlands at successive age classes of 5 y or 10 consecutive y for vertebrates and macroinvertebrates density and richness (A) and for plant density and richness (B). Insufficient data points meeting our plotting criteria (see Materials and Methods) were available to plot for macroinvertebrate richness. The zero value dashed line represents reference wetlands (N, number of data points used to calculate the mean ( $\pm$ SE) per age class; Y, years after restoration. Subscripts are as follows: md, macroinvertebrates density; pd, plant density; pr, plant richness; vd, vertebrate density; vr, vertebrates richness). doi:10.1371/journal.pbio.1001247.g002

restoration were not plotted in Figure 1A because the sample size did not meet our criteria for average points, see Materials and Methods section, on this graph). Since phosphorus storage appeared only slightly changed, the overall lack of recovery of biogeochemical functioning may have been driven largely by the low recovery of the carbon storage and the low accumulation of soil organic matter (see Text S1).

### Effects of Size and Environmental Setting

Comparing wetland recovery trajectories under different conditions may shed light on factors that impede or facilitate recovery. Although biogeochemical responses in both restored and created wetlands were similar, biological structure in created wetlands approached reference conditions more quickly (Figure S3A and S3B; Table S5). Created wetlands may have been engineered to force the initial system towards defined reference conditions [39].

Ecosystem size and local and regional context affect wetland recovery. Large wetlands (>100 ha) appeared to recover their biological structure and biogeochemical functions sooner after restoration or creation than smaller wetlands (Figures 3 and S4; Table S4; data from 13 studies of 25 wetlands). This differential recovery suggests that small wetlands may not provide adequate local resources or connectivity for local biota to restore preimpact functioning. Restored and created wetlands, particularly if small, may have become more isolated and surrounded by more fragmented landscapes than they had been before impact [40]. Also, small wetlands would only be able to support a limited number of individuals, and thus, will not be able to support all the species, particularly taxa with large body sizes, formerly capable of occupying the area [41].

Regional climate had a strong effect on the sequence and rate of wetland recovery following restoration. As expected, warm temperatures accelerate ecosystem processes [7,13,42], including those mediating biological and biogeochemical recovery after wetland restoration or creation. In tropical and summer-warm temperate climates, wetlands approached reference conditions relatively rapidly, while wetlands restored in cold climates had not recovered to reference conditions after 50 y (Figure 4A and 4B; Tables S3 and S5). In tropical climates only, biogeochemical

variables recovered to reference levels before biological structure did (data from eight studies of eight wetlands). Whether this difference in recovery sequence is a real aspect of tropical wetlands, or an artifact of small sample size, remains to be seen. In a much larger sample of studies from temperate climates this sequence was reversed, and biogeochemical recovery was slower. Biological structural variables appeared recovered 5 y after restoration, while even 30 y after restoration, biogeochemical functions had only recovered to 79% of reference levels (data from 83 studies of 302 wetlands). In cold climates, corresponding biogeochemical recovery was only 53% 50 y after restoration; both biogeochemical functions and biological structure variables

**Figure 3. Effect of size on wetland recovery.** Evolution of the mean ( $\pm$ standard error [SE]) of the response ratios (see Materials and Methods) of restored or created wetlands at successive size categories for wetlands between 0 y to 5 y after restoration or creation. The zero value dashed line represents reference wetlands. Mean ( $\pm$ SE) at 0.1 ha was estimated for wetlands with sizes  $\leq$ 0.1 ha. Means ( $\pm$ SE) at 1 ha were estimated for wetlands in which sizes ranged between 0.1 ha and 1 ha. The same approach was used to estimate the means ( $\pm$ SE) at 10, 100, 1,000, and 10,000 ha (N, number of data points used to calculate the mean ( $\pm$ SE) per age class; size, size in hectares of the restored wetlands. Subscripts are as follows: bp, biogeochemical processes; bs, biological structure). doi:10.1371/journal.pbio.1001247.g003

**Figure 4. Effects of climate and hydrology on wetland recovery trajectories.** Chronosequences of the means ( $\pm$  standard error [SE]) of the response ratios (see Materials and Methods) of restored and created wetlands at successive age classes of 5 y or 10 consecutive y for biogeochemical functions and for biological structures under contrasting climates (A and B), and under different hydrologic connectivity (C and D) [31]. The zero value dashed line represents reference wetlands. The arrow (B) indicates the outlier mean value of two restoration studies with extremely low recovery rates (N, number of data points used to calculate the mean ( $\pm$ SE) per age class; Y, years after restoration. Subscripts are as follows: bp, boreal peatland; d, depressional; hc, humid cold; ht, humid temperate; r, riverine; str, seasonal tropical; ste, seasonal temperate; t, tidal). doi:10.1371/journal.pbio.1001247.g004

remained statistically distinct from reference conditions for the entire (50-y) chronosequence (Figure 4A and 4B; Tables S3 and S5; data from 33 studies of 311 wetlands).

Hydrologic setting [43] also affected recovery (Figure 4C and 4D; Tables S3 and S5). Riverine and tidal wetlands, linked to larger hydrologic regimes by natural flow variation, recovered biogeochemical functions and biological structure after 20 y and 30 y, respectively (data from 73 studies of 210 wetlands). These results are similar to those (15 y to 25 y to recover the original biotic composition and diversity) found by Borja et al. [8] in 51 globally distributed estuarine and coastal ecosystems. In contrast, wetlands in inland depressions that were watered by precipitation or groundwater flow had not recovered to reference conditions even after 50 y following restoration (data from 36 studies of 358 wetlands). Peatlands (usually only the upper layer [ $<1$  m] of peat was removed) recovered biological structure immediately, but 30 y after restoration, biogeochemical functioning in peatlands remained statistically lower than in reference wetlands (data from 11 studies of 18 wetlands).

### Slow Recovery or Alternative States?

Two hypotheses could explain the lag in biological and biogeochemical recovery of the biological structure and biogeo-

chemical functioning. First, the chronosequences we examined may be too short ( $<30$  y) for full recovery, especially of carbon and nitrogen storage [44]. Second, restored wetlands may have shifted to alternative states, different from their condition before degradation [14,15]. The subreference plateaus of soil organic accumulation, carbon storage, and general biogeochemical functioning could support the second hypothesis of alternative states in restored systems. Slow recovery of plant density and richness might be linked to lags in carbon storage. Mutualist symbionts critical for plant productivity (e.g., N-fixing bacteria [2] or mycorrhizal fungi [45]) may be absent in recently ( $<50$  y) restored wetland soils. Alternatively, fast-growing, early successional terrestrial plants, and potentially also wetland plants, usually allocate most of their carbon to photosynthetically active structures of low density and high nutrient content, which are easily grazed or rapidly decomposed, retarding local storage of carbon [46,47].

### Comparison with Other Findings

Two other studies have assessed recovery rates of large scale natural ecosystems following disturbance or perturbations [7,12]. Both of these studies examined a broad range of ecosystem types (terrestrial, freshwater, and marine), including wetlands. Jones and

Schmitz [12] found that across ecosystems and perturbation types (natural and human-caused), about half of the tracked response variables were considered by original authors to have recovered to preimpact states. Jones and Schmitz computed averaged recovery times for the subsamples of variables and cases that primary authors considered to have recovered over the course of their studies. These recovery times ranged from about 10 y to 40 y, and were longer for forests, and following human-caused, rather than natural perturbations. To assess whether systems had recovered or not, Jones and Schmitz used authors' expert opinion, return to historic initial conditions, or approach to parallel reference states (our study evaluated recovery only for studies using the last of these criteria). Given the narrower scope of our study (assessing wetlands only), and our different analysis approach, estimated recovery times from these two reviews are surprisingly similar. Rey Benayas et al. [7] studied recovery across a wide range of human-perturbed ecosystems, including wetlands. Using (as we did) the response ratio of restored to reference ecosystems, Benayas et al. found biodiversity and selected ecosystem services to be 86% and 80% recovered in a sample of 89 cases pooled over all age categories since perturbation. Interestingly, they reported slightly (6%) higher recovery in biological variables compared to ecosystem services (nutrient cycling; primary production; provisioning of timber, fish, and food crops; and regulation of climate, water supply, and soil). These ecosystem services overlap in part with categories of biogeochemical variables in our study (e.g., carbon and nutrient storage and cycling). The similarity between their results and our finding (that biological variables were 9% more recovered than these biogeochemical responses) suggests that structural recovery might often be necessary to achieve functional recovery.

## Conclusions

Our meta-analysis suggests that recovery of wetlands following restoration as currently practiced is often slow and incomplete. In warm climates, and in settings linked to riverine or tidal flows, recovery may proceed more rapidly. Recovery may also be more likely and more rapid if >100 contiguous ha are restored. In many wetlands, however, ecosystem services may not be fully recovered even when wetlands appear to be biologically restored. If markets for ecosystem services and mitigation offsets from restored or created wetlands are used to justify further wetland degradation, net loss of global wetland services will continue and likely accelerate (see also Race and Fonseca [48]). We join other wetland ecologists and restoration scientists in calling for better scientific understanding of biotic and abiotic factors that constrain ecosystem restoration. For our common future, we need more realistic, long-term evaluations to find better ways to alleviate constraints limiting the recovery of wetland ecosystems.

## Materials and Methods

### Literature Search

On the 22nd of December 2010 a reference search was done in the scientific database ISI Web of Science – SCI-Expanded. The terms used were “(wetland\* or floodplain\* or peatland\* or marsh\* or mangrove\*) same (restor\* or creat\* or re-creat\* or rehabilit\*)”. We used these terms to cover a wide variety of wetlands as defined in the Article 1.1 of the Ramsar Convention text [7]. For this analysis, we considered restored wetlands to be wetlands recreated on sites where wetlands had formerly existed but been drained or otherwise severely degraded. Created wetlands were described by authors as wetlands built on sites that lacked previous wetland history. We selected studies of wetlands under natural hydrological regimes, planted with native species, and in which no allochthonous

substrates were imported during the restoration or creation activities. For this reason, the term “construct\*” was not included in the search terms, because we found in an independent search that >99% of the studies of constructed wetlands were of highly artificial systems not maintained under natural conditions. The search produced 2,959 selected articles. We applied the general selection criterion: “Articles must compare measurements of structural components and biogeochemical processes in restored or created and reference wetlands at a known age.” Under this criterion we selected 172 articles. These articles were read, and those in which data were averaged over time intervals larger than 5 y, those in which sizes differing by more than one order of magnitude were averaged, and those lacking reliable measurements or comparable restored and reference conditions were discarded, leaving 124 articles (see Text S2). Reference wetlands were usually adjacent to restored or created wetlands, although in some cases they were separated by several kilometers (maximum distance found was ~100 km). In all cases, restored or created wetlands were of the same wetland hydrogeomorphic type [17] as reference wetlands with which they were compared. From the selected articles, six were carried out on experimental wetlands, the rest were carried out on wetland restoration or creation projects. Studies either described measurements at a known age after wetlands were restored or created, or a chronosequence of the progression during the wetland restoration process. Restored and created wetlands were located in 12 countries and totaled >21,294 ha in area and reference wetlands >19,694 ha. The exact total area is not known because it was not reported in 23 out of the 124 selected studies.

### Data Extraction

Measurements of structural components and biogeochemical processes were extracted from the main text, tables, and figures of the articles. When abundance of one species was measured at different life stages, only the adult abundance of each species was selected. Variables describing hydrological structure, biological structure, element storage and cycling, and organic matter accumulation were classified as structural components or biogeochemical processes according to wetland functions described by Smith et al. [42], and as ecosystem services described in the Millennium Ecosystem Assessment (MEA) (organic matter accumulation was sometimes designated as “soil formation” in the MEA but not in other soil science references) [49].

Element storage and cycling variables measured processes (mineralization or denitrification) and concentration of elements in different pools (total content in soil, organic content in soil, or content in roots), which suggest how nutrients are moving between pools through biotic and abiotic processes (Tables S1 and S2). The studies presented enough data points to plot recovery of storage of carbon, nitrogen, and phosphorus.

### Response Ratio Calculation

To standardize and compare data, we used standard response ratios used in meta-analysis,  $\ln(X_{rest}+1/X_{ref}+1)$  [3], where  $X_{rest}$  is the value of the measured variable in the restored or created wetland and  $X_{ref}$  is the value of the measured variable in the reference wetland. To avoid the value “0” in the natural logarithm of the equation, “1” was added to both values in restored or created and reference wetlands. The effect of adding “1” to the values in the response ratio equation has been demonstrated to have little effect on conclusions [50]. The effect size was not weighted because variance was reported for only 64% of the variables. Differences between weighted and unweighted meta-analysis statistics are generally small [7].

As variables depicting structural components and biogeochemical processes in restored or created wetlands converged to values in the reference wetlands, recovery of function was generally enhanced. But for some variables, such as soil bulk density [51,52], or proportions of exotic species [53,54], higher values are associated with lower levels of wetland recovery. In some cases, the specific context of a study made variables negative for recovery of a particular restored wetland, e.g., the presence of woody species where none had occurred in the reference wetlands [55,56]. In these cases (11% of the collected variables), we changed the sign to reverse the value of the response ratio.

## Data Classification

For each variable we recorded the age of the restored or created wetland, the wetland hydrogeomorphic type, the number of restored or created and reference wetlands considered in a given study, the size (ha) of the restored or created and reference wetlands, the initial condition (restored or created), the geographic location, and the climate. Most data (49%) were from wetlands that had been restored or created for less than 5 y (Figure S1). If data from several wetlands of different sizes were averaged in the study, then we also averaged the sizes for our analysis. The geographic location was registered as the latitude and longitude in degrees of the center of the wetland or group of wetlands. The climate was classified according to the last revision of the Köppen-Geiger climate classification [57]. We used the name humid temperate climate for Cf climate, humid cold climate for Df climate, seasonal temperate climate for Cs climate (with dry summer), and seasonal tropical for A climates. Two of our sampled studies were done in seasonal temperate climate with dry winter (Köppen-Geiger climate classification Cw), and were not considered in our climate study. Wetland hydrogeomorphic type was classified according to Brinson [58] and Smith et al. [42] as depressional, riverine, tidal, peatland, lacustrine, and seeping slope. Only three studies were on lacustrine wetlands and one on seeping slope wetlands, so these types were not considered in our study of differences among wetland types.

In studies where more than one wetland was studied and data were available for each individual wetland, data were collected for each wetland. In 27 studies, more than one wetland was compared with the same reference wetland, and in 11 studies, restored or created wetlands were compared with more than one reference wetland. All studies where more reference rather than restored or created wetlands were studied provided only averaged data for both groups of wetlands. We calculated contingency tables between the wetland size, the initial conditions (created versus restored), and the covariates included in the environmental setting section (climate and wetland hydrogeomorphic type), using contingency coefficients ( $C$ ), to test for independence between them. Wetland type showed relevant degrees of association with the climate ( $C=0.63$ ) and wetland size ( $C=0.58$ ), the rest of variables had coefficients below 0.5, indicating low degree of association. These associations may be explained by the influence of the climate on wetland types, e.g., peatlands are usually associated to cold climates, and mangroves to tropical climates. Also, peatlands usually extend over vast surfaces (hundreds or thousands of hectares) and depressional wetlands are usually small basins (less than 10 ha or few tens of hectares).

## Statistical Analysis

Because data were non-normally distributed (according to the Kolmogorov-Smirnoff test for normality), we used Wilcoxon signed rank tests to test for significant deviations from zero (no

difference from reference conditions) for each estimated mean of the response ratios for variables at each age interval of a restored or created wetland. To test for differences between the same variable measured under two different environmental settings at a given recovery time, we used Kruskal-Wallis tests.

## Chronosequences Plotting

To plot the temporal trends, the mean values and the standard error of each variable with every age class of 5 y (0–4.9, 5–9.9, etc) were used. The criterion for a mean for a certain age class to be used in the plot was that it must have been derived from at least nine different data points obtained from at least two different studies. When this criterion was not fulfilled, the mean values and standard error of age classes of 10 y (e.g., 10–19.9, or 20–30) were used. Temporal trend lines were fitted when enough data to calculate means for two or more age classes were available.

**Abstract:** A watershed-based assessment of wetland impacts and compensatory mitigation was conducted for the Cuyahoga River Watershed (CRW) in northeastern Ohio, USA, to explore the effectiveness of wetland mitigation regulations and any resulting cumulative changes to wetland and landscape structure. Mitigation projects from 23 Section 401 certifications and Ohio Isolated Wetland permits were evaluated for permit compliance, wetland structure, and landscape context. Although there was a net gain in wetland area as a result of the 23 permits, the CRW experienced a net loss of wetland acreage due to the exportation to mitigation banks located outside the watershed. The majority of projects (67%) that restored or created wetlands independently (not at a mitigation bank) were not successful at meeting permit requirements in terms of wetland area. The comparison of impacted and mitigation wetland vegetation types revealed an increase in open-water/emergent wetland area and a decrease in area of scrub/shrub and forested wetlands, along with a decrease in the number of wetlands from 134 impacted wetlands to 65 mitigation wetlands. Impacted wetlands were significantly smaller than replacement wetlands. Landscape composition surrounding the wetlands was highly variable, varying from 17%–75% natural land uses and from 18%–82% human land uses. We suggest that an improvement in compliance with permit requirements is necessary. Current wetland policy allows for the exportation of wetlands for mitigation purposes, which can result in the loss of wetlands from some hydrologic units. The consideration of wetland structure needs to be incorporated into the regulatory process to avoid a shift in wetland types that are present. Finally, instead of reviewing projects on a site-by-site basis, a landscape approach should be taken in order to avoid the loss of upland-wetland heterogeneity and the placement of mitigation wetlands in degraded landscapes.

**Key Words:** land use, mitigation, permit compliance, watershed approach

### INTRODUCTION

In the United States, under Sections 401 and 404 of the Clean Water Act (CWA), unavoidable

impacts to wetlands must be mitigated through creation, restoration, enhancement, or preservation of wetlands. Section 404 general permits are issued

by the United States Army Corps of Engineers (U.S. ACOE) for activities considered to have minimal impacts upon waters of the United States. Activities that meet the U.S. ACOE definition of minimal impacts are specific to and described within each general permit, which are reviewed and issued every five years. For those activities that have more than minimal impacts upon waters of the United States, an individual Section 401 State Water Quality Certification is also required. In the state of Ohio, the Ohio Environmental Protection Agency (OEPA) is responsible for issuing Section 401 certifications. The OEPA also issues Ohio Isolated Wetland permits for impacts to those wetlands that do not fall under federal jurisdiction. This program supports the principle of no-net-loss, committed to maintain and eventually increase the area of wetlands in the United States (USEPA-USACE 1990).

After a few decades of implementation, it remains uncertain whether Sections 404 and 401 of the CWA are successful in establishing fully functioning wetlands. Mitigation success is frequently measured by comparing mitigation wetlands to natural "reference" wetlands. These studies often assess changes in the type of wetlands and the plant community being constructed (e.g., marsh, floodplain, scrub/shrub) (Craft et al. 2002, Balcombe et al. 2005c), while others characterize bird communities (Darnell and Smith 2004, Balcombe et al. 2005a, Keagy et al. 2005), aquatic fauna (West et al. 2000, Balcombe et al. 2005b), and biogeochemical processes (West et al. 2000, Craft et al. 2002, Brooks et al. 2005). In diverse locations of the United States, information has also been compiled to assess permit compliance (Texas and Arkansas: Sifneos et al. 1992; Oregon and Washington: Kentula et al. 1992; central Pennsylvania: Cole and Shafer, 2002; Tennessee: Morgan and Roberts 2003; San Francisco Bay region, California: Breaux et al. 2005).

Few assessments have compared the wetlands that were impacted with the mitigation wetlands that replaced them (but see Cole and Shafer 2002, Minkin and Ladd 2003). Such direct comparison is the ideal approach to understanding whether or not mitigation policy is effective (Zedler 1996) but is often challenging because of the lack of records kept on the impacted wetlands (Sifneos et al. 1992). One difficulty in this type of assessment is the analysis of wetland function, especially for impacted wetlands that have already been eliminated for development. Instead, we have to rely upon information that has been collected for these wetlands prior to their destruction. Such information is often limited and lies mostly within assessment reports submitted for Section 401/404 application. Despite these limitations, to understand

the impact of mitigation practices within a region, we must make an effort to compare what is being lost to what is being produced.

The need for a watershed-based approach has also been raised (Bedford and Preston 1988, Zedler 1996, Environmental Law Institute 2004). Watershed and landscape based approaches are recommended because many wetland functions rely upon conditions in the surrounding landscape (Amezaga et al. 2002). Despite this understanding, few studies of wetland mitigation have taken this large-scale approach (but see Kelly 2001, Johnson et al. 2002), probably because many mitigation projects are conducted on a site-by-site basis without considering the broader landscape (Bedford and Preston 1988, Race and Fonseca 1996, Zedler 1996). Wetland impacts and mitigation efforts might result in a spatial re-configuration of wetlands within the landscape (Bedford 1996, Kelly 2001). This re-configuration could include changes in 1) the spatial extent of wetlands including size, number, and location, 2) wetland characteristics such as hydrogeomorphic class or vegetation type, and 3) land uses surrounding wetlands. These re-configurations can be expected to have an impact upon the functions that wetlands are able to provide (Tilton 1995, Faulkner 2004, Houlahan et al. 2006).

In this study, we conducted a watershed-based assessment of wetland mitigation using information from Section 401/404 applications. The lack of data on impacted wetlands limited the comparison of impacted and mitigation wetlands to strictly structural metrics. The objectives of the study were to: 1) assess the level of compliance with permit requirements and net gain/loss of wetland area overall and on a watershed basis; 2) determine whether any changes in wetland structure have occurred as a result of wetland impacts and mitigation efforts; 3) quantify whether the mitigation practice altered the number, size, and density of wetlands; and 4) describe the land uses surrounding mitigation wetlands.

## METHODS

### Permits Assessment

We reviewed the Section 401 certifications and Ohio Isolated Wetland permits issued by the Ohio Environmental Protection Agency (OEPA) for impacts to surface waters within the Cuyahoga River Watershed (CRW). The CRW is located in northeastern Ohio (USA) (Figure 1). The CRW covers an area of 2,106 km<sup>2</sup> of both urban and rural land uses, including a portion of the Cuyahoga Valley National Park. Twenty-three permits issued between January 1, 1995 and January 1, 2003 and

Figure 1. Map of the Cuyahoga River Watershed and locations of impacted and mitigation wetlands associated with the 23 Section 401 and Ohio Isolated Wetland permits issued during the 1995–2003 period.

requiring compensatory mitigation provided the basis for this study (Figure 1). Permits for which wetland were created after January 1, 2003 were excluded to allow sufficient time for wetland characteristics to develop, while permits issued prior to 1995 were not available.

Information regarding the area, location, and type of vegetation of the impacted wetlands, as well as the required wetland area for mitigation, were taken from permit files. Material provided by the applicant in the permit files was used to determine the area of

four vegetation types for each impacted wetland [open-water/submergent vegetation, emergent vegetation, scrub/shrub vegetation, and forested vegetation]. Because many applicants failed to discriminate between open-water/submergent vegetation and emergent vegetation, these two categories were combined for the analysis. Merging the two vegetation types limited our ability to describe certain changes in plant structure and, in particular, to determine whether mitigation practices created deeper/wetter wetlands in the landscape.

### On-Site Mitigation Wetland Survey

Field work was conducted between June 1, 2004 and October 1, 2004. Mitigation wetlands were delineated using the United States Army Corps of Engineers 1987 wetland delineation procedure (U.S. ACOE 1987). Wetland boundaries were mapped using a Trimble GeoXT handheld Global Positioning System (GPS). To standardize coordinate data collection, a point was taken at each location where the wetland boundary turned 10° or more. Point data were later processed and differential correction was conducted using stationary files from the nearest base station. Data were imported into ArcGIS software (ESRI) to calculate wetland area. Percentages of vegetation types (open-water/submergent, emergent, scrub/shrub, and forest) were visually estimated in the field for each wetland.

During the delineation of the mitigation wetlands, two problems were encountered that resulted in an over-estimation of wetland area: 1) presence of deep open-water habitat and 2) existence of wetlands on site pre construction. Two mitigation sites contained deep open-water habitat that was fringed by emergent and submergent vegetation wetland. Given time and methodological constraints, we did not delineate the open-water-wetland boundary. Although the deep open-water areas would not normally be counted for wetland mitigation credit by OEPA, they were included in this study. Additionally, at three other sites, project maps revealed wetlands that were located adjacent to and within mitigation wetland boundaries. Essentially, existing wetlands were expanded during the mitigation construction process. It was not possible to delineate the precise boundary between the natural wetlands and mitigation wetlands, so these areas of natural wetland were included with mitigation area. The information collected at the mitigation sites was compared with the data available on the impacted wetlands in the permit files. This comparison allowed us to calculate net change of wetland area, to determine compliance with permit requirements, and to assess any changes in vegetation types. We also calculated the mandated mitigation ratio (defined as the area of mitigation wetland requested to be built divided by the area of impacted wetland), and the actual mitigation ratio (defined as the area of mitigation wetland actually built divided by the area of impacted wetland).

### Number, Size, and Density of Wetlands

The number and size of impacted wetlands were compared to the number and size of mitigation

wetlands using information from permit files (for impacted wetlands) and GPS data (for mitigation wetlands) for all 23 projects. We assumed that wetland area created at a mitigation bank was located within a single wetland. This analysis was conducted for all projects combined, as well as on a per-project basis. Additionally, for each independent project ( $n = 12$ ), the density of impacted wetlands was compared to the density of mitigation wetlands on a per-project basis using the patch density (i.e., number of wetlands/100 ha) metric in the software FRAGSTATS Spatial Pattern Analysis Program, Version 3.3 (McGarigal et al. 2002; see Kettlewell 2005 for complete description of the method). Impacted wetland polygons were created by scanning and geo-referencing projects maps supplied by the permit holder. Mitigation wetland polygons were created using GPS data collected in the field. For each impacted and mitigation site of all 12 independent projects, landscapes (with only impacted and mitigation wetland land uses) were created with the buffer tool within ArcGIS (ESRI, Inc.) using a buffer of 1,000 m from wetland edges. Mitigation wetlands were created at two different locations for Project #5, resulting in Project #5a and 5b. Wetland density for the two mitigation locations associated with this project was combined.

### Land Use Setting

The availability of high resolution aerial photographs proved to be the limiting resource for assessing land uses around each wetland. Quality aerial photos were only available for recent years, making it impossible to estimate land uses around the impacted wetlands with certainty. Therefore, we focused on describing land use surrounding the mitigation wetlands. Six inch (15.24 cm) resolution, county-level aerial photos taken between years 2000 and 2002 were used to digitize land uses into 13 different classes: agriculture, construction, forest, industrial, mitigation wetland, mowed, oldfield, park, pond, residential, road, waterway, and wetland. Land use classes were eventually grouped into human (i.e., agriculture, construction, industrial, mowed grass, residential, and road), natural (i.e., forest, old field, and park), and surface water (i.e., mitigation wetland, pond, and wetland) categories. Out of the 12 independent projects, eight projects were included in this land use analysis. For this analysis, the two mitigation locations for Project #5 were kept separate, providing a total number of nine projects. Land uses were digitized using ArcGIS (ESRI, Inc.) at a map scale of 1:2000–1:4000 (see Kettlewell 2005 for complete description of the

method). Landscapes were analyzed within the 300-m and the 1,000-m buffers from the edge of mitigation wetlands. The number of wetlands located in 300-m and 1,000-m buffers (excluding and including mitigation wetlands) was also assessed. These two buffers size, while somewhat arbitrary, were selected because they represent local and larger-scale processes that may be critical in maintaining wetland structure and function. The 300-m buffer adjacent to a wetland affects wetland plant diversity (Houlahan *et al.* 2006) and serves as critical terrestrial habitat for reptiles and amphibians (Semlitsch and Bodie 2003, Colburn 2004; Porej *et al.* 2004). For some amphibian species, a 1,000-m buffer is optimum to maintain metapopulations (Vos and Stumpel 1995, Knutson *et al.* 1999; Porej *et al.* 2004).

### Statistical Analysis

Minitab statistical software Version 12.23 was used for all statistical analysis. The significance level was set at  $\alpha = 0.05$  for all statistical tests. Pearson's correlations were used to select landscape indices for various portions of land use analysis and to test whether variance in landscape area affected metric values. A Pearson's coefficient of  $r > 0.700$  or  $r < -0.700$  was used to indicate metrics that were significantly correlated. Two sample t-tests were used to compare impacted and mitigation wetland characteristics when all projects were combined. Paired t-tests were used to compare impacted and mitigation characteristics on a per-project basis. Outliers were identified using the Box and Whisker Plot procedure. The data were log-transformed when necessary to meet the assumptions of the analysis (normality and homoscedasticity).

## RESULTS

### Permit Compliance

Of the 23 projects evaluated, eight were mitigated for wetland losses by purchasing "wetland credits" at various mitigation banks within the Ohio portion of the Lake Erie basin, outside the CRW. One project was mitigated at a bank owned by the applicant within the watershed. Two projects that impacted wetlands within the watershed were mitigated entirely through wetland preservation. Twelve projects relied upon independent creation or restoration efforts to mitigate for wetland losses (*i.e.*, not at a bank). Of these 12 projects, 11 were located within the CRW. Nine of the 12 independent mitigation projects were constructed "on-site," while

three sites were constructed at a location other than the impact site. Sixty-five wetlands were created as mitigation for 134 impacted wetlands. Because several wetlands can be impacted or created for each permit, the number of projects does not reflect the number of wetlands.

For the 23 permits, 14.95 ha of wetlands were lost, 27.78 ha of created wetlands were required, and 26.27 ha of mitigation wetlands were created. The 26.27 ha of mitigation wetlands assumes that requirements for the eight mitigation bank projects were adequately met. The result is a net gain of 11.32 ha of wetlands at an actual mitigation ratio of 1.76:1, while the mandated mitigation ratio was 1.85:1. A total of 5.24 ha (10 projects) of wetlands were purchased from a pooled mitigation bank and 0.77 ha (one project) of wetlands were created within a private mitigation bank. Another 20.26 ha (12 projects) of wetlands were either created or restored by the applicant independently. An additional 2.11 ha of wetland enhancement and 21.30 ha of wetland preservation were proposed, although these areas were not evaluated for compliance. Of the 12 independent projects, the mandated mitigation ratio averaged 3.96:1 and ranged from 1.00:1 to 25.50:1. If one outlier was removed, this ratio decreased to 2.00:1 (ranging from 1.00:1 to 3.54:1). The actual mitigation ratio averaged 3.11:1 and ranged from 0.87:1 to 14.00:1. Once again, if one outlier was removed, this ratio dropped to 2.12:1 (ranging from 0.95:1 to 4.88:1).

Within the CRW, 14.58 ha of wetlands were lost and 11.36 ha of mitigation were created. The remaining 14.91 ha of wetland mitigation were exported from the watershed. Two projects were responsible for 9.67 ha of exported wetland area and 5.24 ha of exported wetland area were the result of purchasing mitigation bank credits. While the mandated mitigation ratio was not significantly different from the actual mitigation ratio on average ( $p > 0.05$ ,  $df = 11$ ,  $t = 0.83$ ), the majority of the 12 independent projects ( $n = 8$ ) did not achieve the required wetland area (Figure 2).

### Vegetation Types

The majority of mitigation wetlands were comprised of open-water/emergent vegetation (82.8%), followed by scrub/shrub vegetation (14.7%) and forested vegetation (2.5%) (Figure 3). Based on information contained in permit files, impacted wetlands were also dominated by open-water/emergent vegetation (42.5%), followed by scrub/shrub (41.0%) and forested vegetation (16.5%). Emergent wetlands were replaced at a ratio of

Figure 2. Percent deviation from the required mitigation wetland area for the 12 independent projects (i.e., projects that did not use a mitigation bank). Projects with bars above the zero line constructed more wetland area than necessary, while those below the zero line failed to meet mitigation requirements.

3.6:1, scrub/shrub wetlands were replaced at a ratio of 0.65:1, and forested wetlands were replaced at a ratio of 0.28:1. If only the mitigation wetland created in the CRW are considered, emergent wetlands were replaced at a ratio of 2.3:1 and scrub/shrub wetlands were replaced at a ratio of 0.03:1 (i.e., all forested wetland impacts were mitigated within the CRW).

Mitigation associated with the 12 independent projects led to an increase in open-water/emergent wetland area per project ( $p = 0.014$ ,  $df = 11$ ,  $t = -2.91$ ) and a decrease in scrub/shrub wetland area ( $p = 0.019$ ,  $df = 11$ ,  $t = 2.75$ ) (Table 1). The change in forested wetland area was not significant. However, an analysis of presence/absence of vege-

Figure 3. Vegetation types of impacted and mitigation wetlands for the 12 independent projects (i.e., projects that did not use a mitigation bank). The wetland areas shown in dark grey were exported to other watersheds.

tation types indicated that forested vegetation was present more often in impacted wetlands than mitigation wetlands ( $p = 0.017$ ,  $df = 11$ ,  $t = 2.80$ ). Changes in the presence/absence of open-water/emergent and scrub/shrub wetlands were not significant.

#### Number, Size, and Density of Wetlands

During this mitigation process, 134 wetlands were destroyed in the CRW, while 50 were created. The decrease in number of wetlands on a per-project basis was not significant; however, when one outlier was removed (Project #12), the decrease became significant ( $p = 0.004$ ,  $df = 21$ ,  $t = 3.26$ ). Project #12 led to the creation of 25 of the 65 mitigation wetlands. Mitigation wetlands ( $n = 65$ ) for all

Table 1. Vegetation types by wetland area for impacted and mitigation wetlands for the 12 independent projects (i.e., projects that did not use a mitigation bank).

| Project #     | Impacted Wetlands   |              |              | Mitigation Wetlands |              |              |

Figure 4. Size-ranked display of all impacted (dark circles) and mitigation (gray diamonds) wetlands for the 12 independent projects (i.e., projects that did not use a mitigation bank). The y-axis shows the area of each wetland. The x-axis ranks each wetland by size showing 65 mitigation points and 134 impacted points. Note that many of the wetlands were very small, with an area close to zero.

projects were significantly larger in area than impacted wetlands ( $n = 134$ ) ( $p = 0.027$ ,  $df = 74$ ,  $t = 2.26$ ; Figure 4). The average size of impacted wetlands was 0.11 ha, and the average size of CRW replacement wetlands was 0.23 ha. If two outliers were removed, the significance became greater ( $p = 0.002$ ,  $df = 66$ ,  $t = 3.21$ ). No difference in wetland density (i.e., number of wetlands/100 ha) was noticed as the result of the mitigation process.

#### Land Use Setting

There was considerable variation in land uses surrounding the nine mitigation projects studied (Table 2). Within the 300-m buffers, natural and human land uses occupied 33% to 75% and 18% to 65% of total landscape area, respectively. At the 300-m level, three projects (Projects #2, 3, and 4) were dominated by human land uses, while five (Projects #1, 5a, 5b, 6, 7, and 8) were dominated by natural land uses. Natural land uses within the 1,000-m landscapes occupied 17% to 59% of the total landscape area and human land uses represented 31% to 82% of the area. At the 1,000-m level, five projects (Projects #2, 3, 4, 5a, and 6) were dominated by human land uses and four (Projects #1, 5b, 7, and 8) were dominated by natural land uses. More specifically, forest was the dominant land use within 300-m and 1,000-m buffers surrounding six of the nine mitigation projects. The second and third most common land uses were residential and oldfield for the 300-m buffers, and residential and industrial for the

1,000-m buffers. Within the 300-m buffers, the number of wetlands ranged from 0 (Projects #3, 4, and 8) to 8, while at the 1,000-m level, the number of wetlands ranged from 0 (Project #4) to 19. When mitigation wetlands were included, the number of wetlands ranged from 1–10 at the 300-m level and from 1–20 at the 1,000-m level.

#### DISCUSSION

Recent studies of wetland permit compliance have re-enforced uncertainties about our abilities to create wetland ecosystems. Some reports highlight that most permit-holders are in compliance with permit conditions (e.g., Cole and Shafer 2002, Minkin and Ladd 2003), while others stress that the majority of permit-holders are unable to successfully meet permit requirements (e.g., Johnson *et al.* 2000, Brown and Veneman 2001). Both net-gains and a net-loss of wetland area have been reported. Our study suggests that, overall, the mitigation process resulted in a net-gain of wetland area. However, the majority of the projects that we reviewed did not meet wetland area requirements, and the CRW experienced a net loss of wetland area. Only 78% of the area of all the wetlands impacted is now present as mitigation wetlands within the watershed, highlighting one of the problems associated with “off-site” mitigation. Because our analysis led to an over-estimation of wetland area (i.e., inclusion of deep open water and of natural wetlands in some mitigation wetlands), the net change of wetland area could have been even more detrimental.

Eight of the 23 projects mitigated for impacts by purchasing wetland credits at a mitigation bank outside of the CRW. Mitigation banks have been designed to allow permit-holders who are impacting small areas of wetland to mitigate for impacts by purchasing “wetland credits” instead of creating or restoring wetlands “on-site” (Reppert 1992). The question then, is to what extent we should allow wetland functions to be trans-located geographically. In Ohio, permit-holders are restricted to using mitigation banks that are located within the same ACOE district (i.e., Buffalo or Huntington) where the impacts occur. Mitigation banks are generally restricted to service areas of one or two 8-digit hydrologic unit code watersheds. However, applicants are permitted to purchase mitigation credits for impacts to lower quality wetlands at banks elsewhere within the same ACOE district (Ohio Administrative Code 3745-1-54). Such authorization of wetland exportation should consider the function and context of the impacted wetlands and the

Table 2. Percentage of human, natural, and water land uses around each wetland mitigation project. Bold numbers indicate the dominant land use for each project. mitigation bank. If the impacted wetlands are functionally inferior and located within a degraded landscape, then their replacement with a higher quality mitigation wetland may be justified. Specific to the watershed we studied, it is worth noticing that a portion of the lower Cuyahoga River has been declared by the International Joint Commission in 1988 as an area of concern. Areas of concern are designed to focus efforts to clean up the most polluted areas of the Great Lakes region. As wetlands ecosystems are well-known to contribute to improving water quality, the net loss of wetland from the CRW is therefore counter-productive to the goal set by the International Joint Commission (1988).

In this study, impacted and mitigation wetlands were both dominated by emergent vegetation and open-water. The percentage of wetlands that were emergent/open-water nearly doubled as a result of mitigation efforts, while the amount of forested and scrub/shrub wetlands both decreased in area. Our classification scheme did not separate between emergent vegetation and open-water, principally because applicants to 401/404 permits did not make this distinction. To provide more detailed information about the impacted wetlands, permit applicants should be encouraged to make a clear distinction

between open water and emergent vegetation. The lumping of open water with emergent vegetation prevents us to conclude on whether mitigation wetlands surveyed in the CRW have more open water than the impacted wetlands. A trend in creating open water systems as mitigation for emergent wetlands has been observed in other areas (Bedford 1996, Gwin et al. 1999, Hoeltje and Cole 2007). Other wetland mitigation studies also have reported a shift from forested and scrub/shrub wetlands to emergent/open-water dominated systems (e.g., Brown and Veneman 2001, Cole and Shafer 2002, Minkin and Ladd 2003). It has been suggested that this shift is occurring because emergent/open-water wetlands are easier to construct than forested or scrub/shrub wetlands (Cole and Shafer 2002, Porej 2003). Construction of a deep open-water/emergent depression also seems to be the most reliable way (Porej 2003, Hoeltje and Cole 2007) to meet the hydrology, soil, and vegetation requirements set forth by the ACOE wetland definition (U.S. ACOE 1987). Such a shift in wetland types is likely to cause a regional shift in biodiversity (Gwin et al. 1999) and probably will be associated with a shift in wetland function (Minkin and Ladd 2003). Despite these concerns, it is worth noting that forested and scrub/shrub wetlands will

take longer to get established than emergent wetlands. In other words, we could hypothesize that the dominance of emergent wetlands over forested and scrub/shrub wetlands might decrease as we allow successional processes to occur.

In addition to change in wetland type, the mitigation process altered the spatial configuration of wetlands in the CRW. Essentially, the landscape is experiencing a consolidation of many small wetlands into fewer, larger ecosystems. The maintenance of a rich distribution of wetlands in the landscape is certainly just as important as maintaining high quality wetlands (Kelly 2001, Amezaga *et al.* 2002). The loss of many small wetlands has consequences upon landscape heterogeneity and metapopulation dynamics (Semlitsch and Bodie 1998) and possibly upon nutrient and water cycles (Kelly 2001). In addition, many of the mitigation wetlands we studied had few wetlands in their surrounding area. This disconnectedness from other wetlands and water bodies in the landscape can have effects on many ecological functions (Amezaga *et al.* 2002).

Our landscape analysis further indicates that there was considerable variation in the type of land uses surrounding mitigation wetlands. A few projects were located in landscapes dominated by human land use. One mitigation wetland, for example, was an open-water wetland located within a suburban housing development. Another mitigation wetland was a fringe wetland surrounding a storm-water retention basin within a very urban area. In contrast, other mitigation wetlands were surrounded with natural land uses, often because of their location within parks. The land use surrounding wetlands can be critical to maintain wetland structure and function, and urban development in many watersheds is a threat to the integrity of many wetlands (Kentula *et al.* 2004). For example, some amphibian species such as mole salamanders (*Ambystoma* spp.) and wood frogs (*Rana sylvatica*) require a large core of upland forest associated with their wetland breeding habitats (Semlitsch and Bodie 2003, Colburn 2004) and urbanization negatively impacts these species (Knutson *et al.* 1999, Houlahan and Findlay 2003). Many amphibian species are maintained within metapopulations, requiring a heterogeneous forest-wetland landscape for population survival. Landscape influences other important characteristics of wetland ecosystems such as exotic plant species distribution and abundance (Ehrenfeld and Schneider 1991), bird community composition (Croonquist and Brooks 1993), and water quality (Houlahan and Findlay 2004). Examining the spatial distribution of wetlands within a watershed and the composition of the adjacent landscapes would allow

for a more comprehensive understanding of the changes resulting from mitigation practices.

## CONCLUSION

Although the permits studied resulted in an overall net gain of wetlands, the CRW has experienced a net loss of wetland area. The majority of mitigation wetlands (and the functions they support) has been exported to other watersheds in the state, as a result of off-site mitigation, including the purchasing of wetland credits from mitigation banks. The net loss of wetland area from the watershed is also partly due to the inability of permit-holders to construct the required amount of mitigation wetland area. More rigorous follow-up and enforcement is necessary to ensure that wetland impacts and permit requirements are being adequately addressed. Permit-holders and regulatory agencies should also consider the locations of wetland impacts and mitigation instead of relying solely upon a site-by-site review. We strongly recommend that agencies consider changing policies to perform mitigation in the watershed from which the wetland was destroyed.

The CRW has experienced a shift in wetland structural characteristics as a result of wetland mitigation efforts. There are fewer, larger wetlands being constructed than are being lost. This shift could indicate an increase in the distance between wetlands and a loss of upland-wetland complexes. Many of the forested and scrub/shrub wetlands that are destroyed are being replaced with emergent vegetation and open-water wetlands. Although these structural characteristics are not measures of wetland function, they could be indicators that some functional changes are occurring both within wetlands and across the landscape. Incorporating landscape setting into the permitting process would allow for a more comprehensive understanding of any changes that are resulting from mitigation efforts. Additional research is necessary to understand how landscape structure affects the functioning of wetlands themselves and their ability to improve downstream water resources.

## ACKNOWLEDGMENTS

This research was supported by the United States Environmental Protection Agency grant number CD97576201-0, the Ohio Environmental Protection Agency, and the School of Environment and Natural Resources at Ohio State University. We are grateful for useful comments provided by anonymous reviewers on an earlier version of this work.

## Abstract

Regulatory biodiversity trading (or biodiversity “offsets”) is increasingly promoted as a way to enable both conservation and development while achieving “no net loss” or even “net gain” in biodiversity, but to date has facilitated development while perpetuating biodiversity loss. Ecologists seeking improved biodiversity outcomes are developing better assessment tools and recommending more rigorous restrictions and enforcement. We explain why such recommendations overlook and cannot correct key causes of failure to protect biodiversity. Viable trading requires simple, measurable, and interchangeable commodities, but the currencies, restrictions, and oversight needed to protect complex, difficult-to-measure, and noninterchangeable resources like biodiversity are costly and intractable. These safeguards compromise trading viability and benefit neither traders nor regulatory officials. Political theory predicts that (1) biodiversity protection interests will fail to counter motivations for officials to resist and relax safeguards to facilitate exchanges and resource development at cost to biodiversity, and (2) trading is more vulnerable than pure administrative mechanisms to institutional dynamics that undermine environmental protection. Delivery of no net loss or net gain through biodiversity trading is thus administratively improbable and technically unrealistic. Their proliferation without credible solutions suggests biodiversity offset programs are successful “symbolic policies,” potentially obscuring biodiversity loss and dissipating impetus for action.

## Introduction

Biodiversity trading programs (which include biodiversity compensation, offsets, banking, and biobanking) have proliferated internationally, and are promoted by policy makers and developers as facilitating both conservation and development. Like programs developed for simpler environmental commodities such as air pollutants (Pedersen 1994), most biodiversity trading has a regulatory or statutory basis that prohibits an activity (e.g., indigenous vegetation clearance, species habitat destruction, filling of wetlands) and later permits it conditionally (Salzman & Ruhl 2000).

As a regulatory incentive mechanism (Figure 1), environmental trading relies on developers’ self-interest and resources in addition to administrative enforcement

(Gustafsson 1998:268). Compared with pure administrative mechanisms (e.g., rules, standards), such market mechanisms are often purported to (1) allocate natural resources more efficiently, (2) satisfy developers better (increase access to resources, reduce compliance costs, and/or enhance green credentials; see Kate *et al.* 2004), and (3) provide improved environmental protection (see Gustafsson 1998; Kroeger & Casey 2007). In trading biodiversity, some programs aim to reduce rates of biodiversity loss (e.g., Lueck & Michael 2003; Chomitz 2004). Others, perhaps increasingly, propose to achieve no net loss or a net gain in biodiversity (e.g., WHOEP 1993; VDNRE 2002; WA EPA 2006).

So far, evaluations suggest that biodiversity trading has not produced its promised biodiversity outcomes. Typically, development proceeds while offsets fall short

**Figure 1** A taxonomy of environmental policy instruments (after Gustafsson 1998).

of goals or are never implemented (for some primary sources see Race 1985; Gardner 1996; Race & Fonseca 1996; NRC 2001; Brown & Veneman 2001; Quigley & Harper 2005a, b; Mack & Micacchion 2006; Gibbons & Lindenmayer 2007; Matthews & Endress 2008; Appendix S1). Such evaluations usually blame failure on inadequate assessment currencies, disregard for exchange restrictions, and poor enforcement. Their authors regularly recommend better currencies, more or different restrictions on exchanges, and better audit and compliance procedures.

We posit that weak technical design and lax enforcement are predictable features of regulatory biodiversity trading, and that sound and well-intentioned ecological advice is unlikely to correct this. We use three insights of Salzman & Ruhl (2000), who (1) provided a three-part analytical framework—currency, exchange restrictions, and review—to predict whether a trading program is likely to protect the environmental goods concerned; (2) recognized that simplicity, measurability, and interchangeability (also called *fungibility* or *substitutability*) determine whether environmental goods can be traded and protected simultaneously; and (3) predicted that in trading a complex, noninterchangeable and poorly measurable resource such as biodiversity, ecological realities, and political factors would combine to ensure inadequate currency, exchange restrictions, and review, to the detriment of that resource.

Our review examines ecological and political science theories that suggest protecting biodiversity in trading is neither technically realistic nor administratively probable. We first consider ecological aspects of recent biodiversity trading practice, using Salzman & Ruhl's framework. We assess the adequacy of currencies, exchange restrictions, and oversight to protect biodiversity, and identify issues ecologists have yet to consider. Next, we use public choice theory to extend Salzman & Ruhl's insights into problems of biodiversity trading administration. While biodiversity trading programs proliferate and advance optimistic promises to protect biodiversity,

core impediments to improved biodiversity outcomes remain largely unrecognized and unaddressed. We consider whether this trend is explained by the effectiveness of “symbolic policies,” (Edelman 1964), and suggest both ecological and political science are relevant for the assessment of biodiversity trading programs and potential alternative policy tools.

## Inadequate biodiversity currencies

The test of a currency's adequacy is “... can [it] capture the significant values exchanged or do some important features remain external to the trades?” (Salzman & Ruhl 2000:614, Table 1). Simple environmental goods are easiest to commodify in currency: for example, a kilogram of sulfur dioxide provides a simple, relatively measurable, and adequate exchange currency for a unit of air pollution. But for biodiversity, there is no simple currency that adequately “... capture[s] what we care about” (Salzman & Ruhl 2000:623) (see also Robertson 2000). Biodiversity—the variety of living organisms—is hierarchical, with levels of organization from genes to ecosystems, an extraordinary number of elements at each level that vary in time and space, and diverse interactions within and between levels (e.g., Gaston 2000). Such complexity makes it exceptionally difficult to measure biodiversity, and to estimate an element's contribution to the whole.

Furthermore, if “what we care about” is persistence of the full variety of life, contributions of different biodiversity elements are noninterchangeable. This noninterchangeability can be conceived of in three different dimensions (Salzman & Ruhl 2000): *type* (e.g., endangered frog habitat is neither equivalent to nor exchangeable for endangered tree habitat; captive-bred subpopulations do not replicate a diverse population gene pool); *space* (e.g., isolated and contiguous habitat patches are not equivalent); and *time* (e.g., genetic bottlenecks alter population characteristics irreversibly; early and late seral stages of an ecosystem type support different species suites).

**Table 1** Assessment framework adapted from Salzman & Ruhl (2000) for biodiversity trading, and examples of pertinent questions

| Component 3. Review adequacy                                                                                                                                                                                                       |                                                                                                      |                                                                                                   |
| <i>"Do review provisions:</i>                                                                                                                                                                                                      |                                                                                                      |                                                                                                   |
| <i>a) Ensure robust valuation of the goods exchanged?</i>                                                                                                                                                                          |                                                                                                      |                                                                                                   |
| <i>b) Ensure fair apportioning of costs and risks (given who stands to gain from the exchange)?</i>                                                                                                                                |                                                                                                      |                                                                                                   |
| <i>c) Effectively counteract agencies' and trading parties' incentives to transact trades that compromise biodiversity?"</i>                                                                                                       |                                                                                                      |                                                                                                   |

Incomplete measurement, imprecise valuation, and noninterchangeability mean biodiversity exchange is strictly not commodity trading, but barter: "individuals haggling over goods and services with unique attributes" (Salzman & Ruhl 2000:614). But unlike barter in private goods, exchanges in environmental goods affect interests beyond direct participants; trading can erode the public's interest in public resources (Gustafsson 1998; Salzman & Ruhl 2000; Kroeger & Casey 2007). Unavoidably, simple biodiversity currencies are inadequate; they facilitate nominal biodiversity accounting, but omit, obscure, or conceal biodiversity features and noninterchangeabilities (Robertson 2000; Salzman & Ruhl 2000; e.g., see Stein *et al.* 2000; McCarthy *et al.* 2004; Fox & Nino-Murcia 2005). And in any exchange, a characteristic not counted is protected only by chance, which facilitates its loss. Simple currencies simultaneously enable poor accountability for biodiversity outcomes and provide opportunity for damage to biodiversity, bringing a need for restrictions on exchanges if public interests are to be protected (Salzman & Ruhl 2000).

### Exchange restrictions to compensate for currency inadequacy

The literature describes many restrictions on biodiversity exchange intended to compensate for currency inadequacies in the three noninterchangeability dimensions.

In each case, a test of adequacy asks: "is this restriction adequate to ensure against biodiversity loss?" (Table 1).

(1) *Type*. Exchanges of dissimilar biodiversity risk loss of biodiversity components and functions (Salzman & Ruhl 2000; ten Kate *et al.* 2004). To counter this problem, some trading programs propose no-go areas to prohibit trading of critical assets (e.g., WA EPA 2006) but permit exchanges of noncritical biodiversity. Others limit exchanges to the same species, communities, or ecosystem type (e.g., VDNRE 2002; Brownlie *et al.* 2007), relying on simplified biodiversity classification tools. Some suggest out-of-kind exchanges ("like for like or better" or "trading up"; ten Kate *et al.* 2004:61; WA EPA 2006:10; Brownlie *et al.* 2007:6) might offer greater value if affected biodiversity is secure and more imperilled biodiversity is protected, although credible guidelines based on measures of complementarity (Justus & Sarkar 2002) have been slow to emerge.

(2) *Space*. The location of individuals, populations, and communities profoundly influences ecological interactions and biodiversity persistence (Hanski 1998); and ecosystems in different locations serve dissimilar functions (e.g., Mitsch 1998). To maintain biodiversity, exchanges must replace ecological interactions and functions lost in development, and restoration projects must not displace other natural ecosystems. Yet quantifying spatial dependency is data demanding, even for single species (e.g., Ovaskainen & Hanski 2004), and adverse effects of spatial displacement are poorly recognized and

rarely remedied in biodiversity trading. Some programs use a rule-of-thumb preference for nearby replacements over distant ones (ten Kate *et al.* 2004). Others restrict trades to within geographic zones (e.g., wetland service areas; Salzman & Ruhl 2000), or concentrate replacements in aggregated sites, intending to overcome fragmentation (e.g., Fox & Nino-Murcia 2005). Still others apparently ignore the problem (see Burgin 2008).

(3) *Time*. Development is usually permanent, life cycles of companies are finite, and ecosystem reconstruction seldom, if ever, succeeds in structure, composition, or function (e.g., Zedler & Callaway 1999; Hilderbrand *et al.* 2005; Quigley & Harper 2005a, b; Morris *et al.* 2006; Gibbons & Lindenmayer 2007; Matthews & Endress 2008). Even temporary losses may permanently damage populations and engender or aggravate cumulative effects. To provide certainty that development will not cause biodiversity loss, new, equivalent habitat must be created before existing habitat is destroyed or modified (Veltman 1995; Crooks & Ledoux 2002). This would restrict exchanges to a few, simple, predictable, quickly maturing ecosystem types (Morris *et al.* 2006). In biodiversity trading practice, time noninterchangeability is dealt with in three ways. First, *permanent drawdown* trading overlooks it, and exchanges destruction of existing ecosystems or species habitats for improved protection of other, existing ecosystems or habitats (as in USA's conservation banking) (Fox & Nino-Murcia 2005; Carroll *et al.* 2008) and Brazil's forest set-aside trading (Chomitz 2004)). Second, *interim drawdown* programs permit ecosystem or species habitat destruction before reconstruction (e.g., Australian states; VDNRE 2002; Gibbons & Lindenmayer 2007). Such programs generate immediate ecosystem or habitat loss, interrupt ecological processes (see Fig. 4 of Gibbons & Lindenmayer 2007:30), and risk permanent loss through restoration failure (Moilanen *et al.* 2008). Third, *true banking* programs nominally address time noninterchangeability by requiring biodiversity replacement before development occurs. This eliminates interim biodiversity loss and risk of restoration failure (though such requirements appear to be seldom enforced; see Salzman & Ruhl 2000; Mack & Micacchion 2006).

## Further ecological problems

The above scan reveals persistent deficiencies in information and practice that facilitate net biodiversity loss through nonequivalent exchanges. Further problems span all three noninterchangeability dimensions. For example, the biodiversity data needed to inform exchange restrictions usually exceed those that governments, developers, or habitat bankers have been willing to fund.

Less comprehensive data bring greater uncertainty about biodiversity characteristics and hence increase potential for biodiversity loss. Also, researchers developing exchange restrictions at project scales often overlook cumulative (often nonlinear, synergistic, and indirect) negative effects of multiple nonequivalent exchanges in type, space, or time (Bedford & Preston 1988; Quigley & Harper 2005a; Mack & Micacchion 2006; but see Brownlie *et al.* 2007; Vesik *et al.* 2008). Another problem concerns ratios (or multipliers) applied to compensate for noninterchangeability in type, space, or time. Some have a statistical or ecological basis. For example, high offset ratios are needed to avoid risk of unfavorable biodiversity outcomes when restoration effectiveness is uncertain, failure is correlated among sites, or restoration is delayed (Moilanen *et al.* 2008). Brownlie *et al.* (2007) recommend multipliers to protect specified minimum areas, addressing the question "what ratio will achieve the biodiversity outcome sought?". Elsewhere, the basis for multipliers seems unsound: providing several times something different cannot replace a lost species or unique ecosystem; restoring something to higher abundance later may not compensate for consequences of a loss now. Similarly, financial insurance can neither restore the unrestorable nor remedy permanent loss.

## Oversight of biodiversity barter

The currency and exchange inadequacies that beset biodiversity barter place a heavy burden on precautionary oversight (a review mechanism) to control exchanges sufficiently to protect biodiversity. Salzman & Ruhl (2000) suggest adequate oversight should ensure meaningful valuation of the public goods exchanged and fair apportioning of costs and risks, and counteract the agencies' and trading parties' incentives to transact bad deals (Table 1). Time and again, researchers report procedural and enforcement failures in biodiversity trading programs, and urge improvement, through more or better frameworks, resourcing, or insurance (e.g., Gibbons & Lindenmayer 2007; Matthews & Endress 2008; Norton 2008). But these suggestions do not address the political and administrative causes of inadequate review.

## Administrative problems

Salzman & Ruhl (2000) observed an administrative playing field of biodiversity barter tilted toward development. We propose that classic theories of politics predict this tilt, and that biodiversity's poor measurability and noninterchangeability exacerbate it. Together, political, and

ecological factors create two fundamental problems for public administration of biodiversity barter:

(1) *Thin markets*. For a viable trading program to operate in practice, currencies must be simple, review cannot be onerous, and restrictions must be straightforward and few (Pedersen 1994; Salzman & Ruhl 2000). But to protect biodiversity, high-quality data must inform precautionary exchange restrictions. Such restrictions create transaction costs and allow few exchanges, constraining an otherwise well-supplied trading market (Salzman & Ruhl 2000; see e.g., Chomitz 2004).

(2) *Inequality, divergence, and coincidence of interests*. Precautionary exchange is also unlikely because of the unequal power and different goals of participants. This is foreseen by the public choice theory of politics, which predicts that rational actors act in their own self-interest, and that some actors are more powerful than others (e.g., see McCubbins *et al.* 1987; Eskridge 1988). Specifically, the motivated few will be more powerful than the disorganized many (Olson 1965); so public choice theory predicts private interests—such as developers—will often defeat public interests—such as biodiversity protection—and reap most policy benefits. As Eskridge (1988:294) observed, “[t]he legislative market is one that works badly. The public goods that government ought to be providing ... are seldom passed by the legislature, because demand for them is usually not strong and legislators gain too little from sponsoring them ... Conversely, rent-seeking statutes – primarily, concentrated benefit, distributed cost measures – seem inevitable.”

Three interests compete in biodiversity barter:

(a) *Traders* (developers and restoration/offset providers) have a financial, or vested, interest in obtaining permits to conduct business. Such traders in environmental goods need not be conscious of the quality of environmental outcomes if a permit is forthcoming (Gustafsson 1998; Floumoy 2000; Salzman & Ruhl 2000; Kroeger & Casey 2007). This encourages developers seeking permits to underestimate (perhaps unintentionally) environmental impacts, and restoration providers to exaggerate (maybe unwittingly) the value of biodiversity goods offered in exchange. Neither trader profits from investment in data to support independent assessment, robust exchange restrictions, and meaningful review. Instead, they benefit from simple currencies that are inexpensive to measure, plentiful trading options with few exchange restrictions, and limited review to minimize risk that a permit will be overturned.

(b) *Biodiversity protection interests* usually have no vested interest in biodiversity barter. They benefit from exchanges that are fully measured, exchange restrictions that are robust and upheld, and review mechanisms that are meaningful and effective in protecting biodiversity.

(c) *Regulatory officials* are those appointed to enforce trading conditions, and are both referee and representative of the public's interest in biodiversity. Because traders have little incentive to control quality, officials shoulder the full burden of enforcement. But officials are not disinterested “billiard balls,” faithfully implementing democratically determined rules (Wilson 1989:88). Without inferring corruption or malfeasance, public choice theory predicts that officials often have motivations that are different from their statutory mandates, and that, given freedom to choose, officials will often pursue their own self interest (e.g., Niskanen 1971; McCubbins *et al.* 1987; O'Toole 1988). In environmental regulation, incentives on officials often coincide more strongly with development than environmental interests: Winter (1985) even suggests that governments rarely fund full enforcement, and sometimes directly discourage officials from frustrating powerful vested interests. Therefore, officials can and sometimes do reduce their financial or political costs by offering development interests more palatable and less environmentally demanding options (Winter 1985; Salzman & Ruhl 2000:648–665; Brower 2008:20–22; 84–108). Simple inexpensive biodiversity currencies, weak or ambiguous exchange restrictions, and limited review benefit both officials and traders because they are cheap and offer flexibility, or utility (see Pedersen 1994; Parkes *et al.* 2004). Coincidentally, they also facilitate development at the expense of biodiversity.

The playing field on which these interests compete is far from level; the “default setting” (Brower 2008:14) predicted by Olson (1965) is that development will defeat biodiversity. To address biodiversity decline, policy instruments must level this playing field. But theory predicts biodiversity barter will reinforce, rather than correct, this default setting.

First, mandates to barter biodiversity weaken existing statutory constraints on biodiversity harm by allowing officials discretion to circumvent them; for example, the Habitat Conservation Plan provision of the USA's Endangered Species Act erodes its absolute prohibition on

species take (Ruhl 1999). Even in situations of routine noncompliance, legitimizing barter may produce worse environmental outcomes than policy regimes in which officials barter with developers “outside the shadow of the law” (Ellickson 1991:52), but the existence of a clear statute constrains their bartering leeway (see Winter 1985:240). More generally, in giving officials discretion to work toward unspecified outcomes, barter increases opportunity for officials already motivated to “skip rather lightly past avoidance and minimization and proceed instead directly to compensation” (Bean & Dwyer 2000:10537), while reducing public power to specify rules and goals through democratic processes (see Salzman & Ruhl 2000:683).

Second, the case-by-case decision making inherent in biodiversity barter reinforces dominance of vested development interests by constraining the effectiveness of biodiversity protection interests. Case-by-case decision making keeps biodiversity loss off the national radar and limits its importance, hence weakening the environmental voice (see Schattschneider 1960; Pralle 2006). It is more costly and less feasible for environmental interests to marshal the resources to challenge proposals case-by-case than through high-level orchestrated campaigns (Brower 2008:57).

Third, problematic measurement and case-by-case barter each render biodiversity trading especially vulnerable to *information asymmetry*—the situation in which insiders (traders and officials) know more than outsiders (biodiversity protection interests and the public), who are unable to measure the quality of biodiversity deals. Information asymmetry creates slack, or “a zone of freedom of action for regulators...in which they can operate with lessened fear of punishment by the polity for decisions that deviate from those the polity would adopt on its own” (Levine 1998:269). When officials’ and developers’ interests coincide in negotiating permits, a pattern of informal and less-than-transparent deals can result (Winter 1985; Freeman 2000; Brower 2008) with norms of behavior and standards of fairness that benefit insiders, but deviate from statutes and ideas of fairness held to protect outsiders—the public (Ellickson 1991). Thus, information asymmetry will systematically favor development over protection.

### No net loss as symbolic policy

Absence of opportunity for public input in case-by-case decisions often renders ecological scientists the most vocal critics of biodiversity trading. But scientists appear reluctant to abandon hope that biodiversity offsets might yet deliver no net loss (see Gibbons & Lindenmayer 2007;

Burgin 2008; Norton 2008). We see compelling reasons for skepticism.

Some ecologists insist biodiversity barter could achieve no net loss—if only there were better currencies, informed exchange restrictions, and attention to review (e.g., ten Kate *et al.* 2004; Gibbons & Lindenmayer 2007). They assume that if improved information and measures were available, and rules were clear and transparently defensible on ecological grounds, officials would use and implement them. Empirical evidence shows that officials have repeatedly failed to do so (e.g., Salzman & Ruhl 2000; Fox & Nino-Murcia 2005; Burgin 2008); and public choice theory predicts this failure. Others might see opportunities to leverage funds for improved biodiversity data and measurement; developers, agencies, and governments are likely to resist this. Those recognizing the primacy of administrative problems posit carefully designed review might counter motivations of traders and officials (Salzman & Ruhl 2000:693). But this would constrain exchanges to the detriment of developers and officials, and no such review institution has emerged. In the absence of credible solutions to these problems, biodiversity trading is likely to continue to facilitate development at the expense of biodiversity.

In addition, biodiversity exchange has potential to postpone social and legislative changes needed to address the basic problem of biodiversity loss (see Pedersen 1994; Gustafsson 1998:271). We see two reasons. First, bartering focuses parties’ attention on immediate steps, rather than stimulating them to proceed “according to some larger progressive principle” (Winter 1985:246). This resembles displacement behavior in which “organizational means become transformed into ends-in-themselves and displace the principal goals of the organization” (Merton 1957). Conservation programs with a preference for near-term, achievable, procedural goals can deflect attention from long-term, more difficult goals for ecological outcomes (Brower *et al.* 2001).

Second, no net loss and net gain slogans themselves may be effective political diversions. We have argued that achieving no net biodiversity loss through barter is an illusion that crumbles under scrutiny from ecological and political science. But Edelman (1960, 1964) suggests that some policies are never intended by politicians to be more than hollow promises. Such symbolic policies promise much but guarantee little, and allow the motivated few to reap most of a policy’s benefits while leaving the disorganized many unaware, or lulled into “political quiescence” (Edelman 1964). No environmentalist will disagree with the goal of no net biodiversity loss. In attaching the slogan “no net loss” to biodiversity barter, politicians can appear to take action while continuing to serve development interests, and ignoring or perhaps

exacerbating biodiversity loss. In engaging ecologists' collaboration in a symbolic but illusory goal, biodiversity barter may succeed by "keeping friends close and enemies closer" (Brower 2008:58) thus defusing potential opposition (Robertson 2000). Developers, politicians, and officials embrace biodiversity barter under "no net loss" or "net gain" flags (Robertson 2000; Salzman & Ruhl 2000; Burgin 2008) because it benefits them to do so. Support from ecological scientists, whether tacit or active, sustains and authenticates the illusion.

## Conclusions

Viable biodiversity barter and meaningful biodiversity protection seem mutually exclusive. We can achieve one or the other, but not both. Although compensation and no net loss are laudable ideals, ecological and political problems appear intractable, and mean that bartering is likely to accomplish more harm than good for biodiversity.

Ecological and political factors combine in bartering biodiversity to produce currencies, exchange restrictions, and oversight that are inadequate to protect biodiversity. Because biodiversity is complex and its elements noninterchangeable, there is no simple currency to measure fairness of exchange, and restrictive exchange rules and robust review institutions are needed to protect it. But a functioning exchange program requires simple currencies, few restrictions, and undemanding review. This gulf between market and ecological viability seems to render biodiversity trading doomed to fail—more specifically, to fail biodiversity. Indeed, the simplistic currencies, lax exchange restrictions and inadequate review that benefit both traders and officials are predicted by political theory and observed in practice. All come at a cost to biodiversity.

We further conclude that inequalities, divergence, and coincidence among interests in biodiversity barter mean that improved biodiversity measures and exchange restrictions recommended by ecologists will rarely be adopted. Few academics and practitioners have understood and tried to address these nonecological causes of failure (Salzman & Ruhl 2000:693).

The administrative playing field described in this article shapes the outcomes of not only biodiversity trading, but also all environmental policy. However, political theory predicts that biodiversity exchange policies—because of biodiversity's complexity, poor measurability, and noninterchangeability—will be more vulnerable to the institutional failings that undermine environmental protection than simple (albeit imperfectly enforced) prohibitions. Public choice theory suggests officials and

traders have more incentive to facilitate barter than to ensure biodiversity protection. Thus, given the option of saying to developers "yes, with conditions" rather than "no," officials will prefer "yes, with conditions"—particularly when compliance with conditions cannot be credibly measured and officials can avoid accountability for outcomes. Legitimized bartering can thus create a policy situation "obscure enough to please all parties ... and so ill-defined that failures ... will be difficult to detect and impossible to litigate" (Walker *et al.* 2008:226; see also Winter 1985).

Furthermore, recent proliferation of offset programs, with the promise of no net loss or net gain, is consistent with effective use of symbolic policy to "give the rhetoric to one side and the decision to the other" (Edelman 1960:703). Symbolic policy may cost conservation by obscuring biodiversity loss and dissipating impetus for social activism and forthright conservation planning.

In sum, while compensation and no net loss are worthy goals, and bartering biodiversity might appear more promising than simple and weakly enforced prohibitions, this article suggests policies that enable biodiversity trading may perversely yield worse biodiversity outcomes. All theoretical predictions point to further biodiversity loss paving the way for development in any biodiversity trading program, while a no net loss tag-line defuses potential opposition and impetus for change.

## Acknowledgments

The authors acknowledge funding from New Zealand's Ministry of Research, Science and Technology, Lincoln University, and in-kind support from the Department of Conservation. We thank C. Bezar for technical editing and four anonymous reviewers for comments that improved the manuscript. We drew on the ideas of many colleagues, especially J. Overton (Landcare Research), B. Napp (Department of Conservation), and S. Bekessey, B. Langford, A. Moilanen, H. Possingham, and R. Pressey (the Applied Environmental Decision Analysis hub).

## Summary

This publication replaces *Wetlands & CAO Updates: Guidance for Small Cities (Western Washington Version)*, Publication No. 10-06-002, January 2010. It also replaces the 1<sup>st</sup> revision dated July 2011 and the 2<sup>nd</sup> revision dated October 2012.

This new publication, for the most part, contains the same guidance as the “small cities guidance” referenced above. Over the last few years, it became obvious that the information in that document could apply to all cities and counties, not just small cities. However, the wetland buffer table may be too restrictive for county use because it assumes that adjacent land use intensity is high. Counties and larger cities generally have more staff and resources that allow more sophisticated approaches to assigning wetland buffers.

In addition, these jurisdictions may be able to provide additional protection for habitat function by requiring protected wildlife corridors between the wetland and other priority habitats in exchange for buffer reduction—something that is often impossible in small, urban jurisdictions.

Check with Ecology wetland staff for more information about using this guidance in your particular jurisdiction <http://www.ecy.wa.gov/programs/sea/wetlands/contacts.htm>.

Specific changes to this new publication include:

- Reference to the updated 2014 wetland rating system
- Updated definitions based on the updated 2014 wetland rating system
- Buffer tables that include habitat scores from the updated 2014 wetland rating system
- Addition of buffer table to be used if minimizing measures are not used
- Emphasis on the requirement to provide wildlife corridors where possible in exchange for buffer reduction
- Guidance on using wetlands for stormwater management facilities
- Revisions to exemptions for small wetlands
- Recommended language addressing agricultural activities in non-VSP jurisdictions
- Addition of recent mitigation documents and guidance
- Corrected links to resource documents and web pages

## Introduction

This document is intended to provide guidance and tools useful in developing a wetland protection program for jurisdictions that are in the process of updating their critical areas ordinances (CAOs) to meet the Growth Management Act (GMA) requirements. Wetlands are one of the five types of critical areas identified in the GMA.

We recognize that many local governments lack the planning staff and resources necessary to develop and implement wetland standards that are both locally appropriate and based on best available science (BAS). Nonetheless, they must comply with the GMA requirement to designate and protect wetlands.

The first part of this document describes the important topics that should be addressed in the wetlands section of your CAO. It includes recommendations for wetland protection based on BAS. Appendix A is a sample CAO chapter for wetlands that incorporates these recommendations into a format similar to that found in many local CAOs. (Please note that the sample CAO will need to be tailored to your jurisdiction's naming and numbering system. There are several generic "XX" references throughout the text.) Appendix B contains definitions that are commonly used in wetlands regulations.

This document does not include the more general provisions typically found in regulations related to all critical areas. These can be found in Appendix A of the *Critical Areas Assistance Handbook* published by the Washington State Department of Commerce (formerly the Department of Community, Trade, and Economic Development) in November 2003 <http://www.commerce.wa.gov/Documents/GMS-Critical-Areas-Appendix-A-Sample-Code-Provisions.pdf>. This document revises the wetland-specific provisions in the *Critical Areas Assistance Handbook*.

The recommendations in this document and the sample ordinance may not be appropriate for use by rural **county** governments. Factors to consider are the county's rate of growth, the nature and intensity of land uses in the county, the wetland resources at risk, and the ability of the county to implement its CAO. We suggest that you contact us to determine whether this guidance is applicable to your county. Please use the following link to find Ecology's wetland specialist for your area:  
<http://www.ecy.wa.gov/programs/sea/wetlands/contacts.htm>.

## Guidance on the Science of Wetland Protection

Ecology has produced several different tools that can help local governments develop a comprehensive wetlands protection program for their jurisdictions. The Washington Departments of Ecology (Ecology) and Fish and Wildlife (WDFW) have published a two-volume guidance document to help local governments protect and manage wetlands:

- ***Wetlands in Washington State, Volume 1: A Synthesis of the Science*** (Washington State Department of Ecology Publication #05-06-006, Olympia, WA, March 2005). This volume is the result of an extensive search of over 17,000 scientific articles and synthesizes over 1,000 peer-reviewed works relevant to the management of Washington's wetlands.
- ***Wetlands in Washington State, Volume 2: Managing and Protecting Wetlands*** (Washington State Department of Ecology Publication #05-06-008, Olympia, WA, April 2005). This volume was developed with the assistance of local government planners and wetland consultants. It can be used to craft regulatory language that is based on BAS. We recommend that you review Chapter 8 and its appendices as you begin to work on updating your existing regulations. (Please note: Appendix 8-C was revised in October 2014.)

In October 2013, Ecology released an update of the science pertaining to wetland buffers. The new information on buffers provides a refinement of our knowledge and revisits the conclusions and key points in the 2005 synthesis.

- ***Update on Wetland Buffers: The State of the Science*** (Washington State Department of Ecology Publication #13-06-011, Olympia, WA, October 2013).

Ecology, in coordination with the U.S. Army Corps of Engineers (Corps) and the U.S. Environmental Protection Agency (EPA), has also developed a two-part guidance document aimed at improving the quality and effectiveness of compensatory mitigation in Washington State:

- ***Wetland Mitigation in Washington State – Part 1: Agency Policies and Guidance (Version 1)*** (Washington State Department of Ecology Publication #06-06-011a, Olympia, WA, March 2006). Part 1 provides a brief background on wetlands, an overview of the factors that go into the agencies' permitting decisions, and detailed guidance on the agencies' policies of wetland mitigation, particularly compensatory mitigation. It outlines the information the agencies use to determine whether specific mitigation plans are appropriate and adequate.
- ***Wetland Mitigation in Washington State–Part 2: Developing Mitigation Plans (Version 1)*** (Washington State Department of Ecology Publication #06-06-011b, Olympia, WA, March 2006). Part 2 provides technical information on preparing plans for compensatory mitigation.

Ecology has also developed a wetland ratings system for western Washington. The rating system is a useful tool for dividing wetlands into groups that have similar needs for protection.

- ***Washington State Wetland Rating System for Western Washington: 2014 Update*** (Washington State Department of Ecology Publication #14-06-29, Olympia, WA, October 2014).

Links to all of these documents can be found at:

<http://www.ecy.wa.gov/programs/sea/wetlands/gma/index.html>.

## **Relationship between the GMA and the SMA**

You may be planning to adopt a Shoreline Master Program (SMP) that will rely on the CAO for protection of wetlands and other critical areas in shoreline jurisdiction. Ecology does not have an approval role in the CAO adoption process; our role is advisory. The SMP, however, is a joint document of Ecology and the local government requiring Ecology approval. Before the SMP can be approved by Ecology, the CAO must meet the “no net loss of ecological functions” requirement (WAC 173-26-186(8)(b)(i)).

You should be aware that the Shoreline Management Act (SMA) may preclude or alter the administration of your CAO. For example, certain activities exempted under the CAO will not qualify for exemption under the SMP. In addition, activities allowed without permits under the CAO may require permits under the SMP.

For assistance with CAO-SMP integration, please use the following link to find the shoreline planner for your area:

<http://www.ecy.wa.gov/programs/sea/sma/contacts/index.html>.

## **Policy Discussion for Your Wetlands Chapter**

Your wetlands chapter will exist as one of several in your critical areas ordinance. Below we describe some of the important subsections in the wetlands chapter and include our recommendations for protecting wetlands based on the best available science.

### ***Purpose***

The chapter typically begins with a purpose statement, followed by designation criteria, which include a definition of wetlands and the methods by which they are identified and rated and other details listed below. The purpose statement may also state that this chapter is intended to be consistent with the requirements of 36.70A RCW and to implement the goals and policies of your Comprehensive Plan for protecting wetlands.

### ***Definitions***

Your wetlands chapter may include a separate list of definitions, or the definitions may be included in the general definitions section of the CAO. Appendix B is a list of

definitions relevant to your wetlands chapter. This list includes terms identified in state law and agency guidance documents. Clarity and consistency in the use of these terms will make ordinance implementation easier.

### *Identifying, Designating, and Rating Wetlands*

The first steps in regulating wetlands are to define what is being regulated and specify how these areas will be identified. The GMA requires the use of the following definition of wetlands and specifies how to identify and delineate them.

In designating wetlands for regulatory purposes, **counties and cities are required to use the definition of wetlands in RCW 36.70A.030(21):**

*“Wetland” or “wetlands” means areas that are inundated or saturated by surface water or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas. Wetlands do not include those artificial wetlands intentionally created from non-wetland sites, including, but not limited to, irrigation and drainage ditches, grass-lined swales, canals, detention facilities, wastewater treatment facilities, farm ponds, and landscape amenities, or those wetlands created after July 1, 1990, that were unintentionally created as a result of the construction of a road, street, or highway. Wetlands may include those artificial wetlands intentionally created from non-wetland areas created to mitigate conversion of wetlands.*

Wetlands are subject to a local government’s regulatory authority if they meet the criteria in this definition. This includes Prior Converted Croplands (PCCs) and isolated wetlands. These wetlands can provide critical functions and habitat and should be regulated. **The GMA does not allow flexibility in adopting a modified definition of wetlands.**

Irrigation practices, such as the Irrigation District ditches in Sequim, can result in human-created wetlands. More frequently, however, irrigation practices may augment natural sources of water to a wetland. Wetlands that form along irrigation ditches that were intentionally created in uplands may be exempted from regulation. However, if a wetland is the unintentional by-product of irrigation activities, the wetland should be regulated. If a wetland disappears as the result of a change in irrigation practice, it will not be regulated in the future. However, most wetlands will not disappear completely as a result of local changes in irrigation practices because of natural sources of water or regional irrigation influences. Please see <http://www.ecy.wa.gov/programs/sea/wetlands/irrigation.html> for more information on how Ecology regulates irrigation-influenced wetlands.

Ecology is most concerned about those changes in land use that would eliminate wetlands as the result of fill or grading, such as a conversion to commercial or residential use. These activities should be regulated by the CAO, and appropriate protection standards

(such as buffers and mitigation) should be required in order to minimize the loss of wetland area and function.

Many jurisdictions use the National Wetland Inventory (NWI) to determine whether wetlands exist within their boundaries. Since the NWI is based on photographs that are over 30 years old and provides only a general approximation of wetland location, it cannot be used alone to designate wetlands. Wetlands are those areas that meet the above definition of “wetland.” Wetlands are also dynamic systems that change over time. It is important to adopt the GMA definition and to have regulations in place to protect wetland functions and values, should wetlands that do not currently appear on the NWI or other maps be identified in the future.

State laws require that wetlands protected under the GMA and the SMA be delineated using a manual that is developed by Ecology and adopted into rules ([RCW 36.70A.175](#); [RCW 90.58.380](#)). The Department of Ecology adopted a wetland delineation manual in 1997 ([WAC 173-22-080](#)) that was based on the original 1987 Corps of Engineers manual and subsequent Regulatory Guidance Letters.

During the last few years the Army Corps of Engineers has updated and expanded their delineation manual with regional supplements. To maintain consistency between the state and federal delineations of wetlands, Ecology has repealed [WAC 173-22-080](#) (the state delineation manual) and replaced it with a revision of [WAC 173-22-035](#) that states that delineations should be done according to the currently approved federal manual and regional supplements. **The changes became effective March 14, 2011.**

The GMA states that “wetlands regulated under development regulations adopted pursuant to this chapter shall be delineated in accordance with the manual adopted by the department pursuant to [RCW 90.58.380](#).” RCW 90.58.380 allows the Department of Ecology to adopt rules that incorporate changes to the manual. **Therefore, the currently approved federal manual and regional supplements should be used for delineating wetlands in GMA jurisdiction.** See: <http://www.ecy.wa.gov/programs/sea/wetlands/delineation.html>.

Local governments are not required to rate or classify wetlands when regulating them. However, methods that classify, categorize, or rate wetlands help target the appropriate level of protection to particular types of wetlands and avoid the “one-size-fits-all” approach. If a local government uses a wetland rating system, it must consider the criteria described in [WAC 365-190-090\(3\)](#).

The *Washington State Wetland Rating System for Western Washington: 2014 Update (Effective January 2015)*, (Ecology Publication #14-06-029, October 2014) is a useful tool for dividing wetlands into groups that have similar needs for protection. The revised rating system represents the best available science, as it is based on a better understanding of wetland functions, ways to evaluate them, and what is needed to protect them. It provides a quick “snapshot” characterization of a particular wetland. In many cases, it will provide enough information about existing wetland functions to allow

adequate plan review and land use decisions to be made without the additional expense of a separate wetland functional assessment.

**While local governments are not required to use Ecology’s revised rating system, we strongly encourage you to adopt wetland regulations that require its use.** Most qualified wetland specialists are using the revised rating system. In cases where state and federal permits are required, the use of this rating system would benefit applicants by eliminating the need to rate wetlands according to a different local standard. If you choose not to use the state’s wetland rating system, you must provide a rationale for this decision according to [WAC 365-190-090\(3\)](#).

We recommend that you include language that describes the four categories of wetlands. This text is different for eastern and western Washington jurisdictions. Please refer to Appendix A, Section XX.020.B.1-4 for the specific category descriptions.

### *Regulated Uses and Activities*

Your wetland section should list those uses and activities that are regulated under the critical areas ordinance. Some of these items include: removal, excavation, grading, or dredging of material of any kind; draining, flooding, or disturbing of the wetland, water level, or water table; the construction, reconstruction, demolition, or expansion of any structure; etc. More extensive examples are provided in the sample ordinance.

Wetlands are often impacted by unauthorized **clearing and grading** that takes place before application for development permits. You should make sure your CAO adequately regulates clearing and grading. If it doesn’t, you should adopt a separate clearing and grading ordinance. The Department of Commerce (formerly Community, Trade and Economic Development) published technical guidance on developing a clearing and grading ordinance: <http://www.commerce.wa.gov/Documents/GMS-Clearing-and-Grading-Technical-Guidance-Final-2005.pdf>.

Most forest practices (as defined in [RCW 76.09](#)) are exempted from the provisions of a wetlands chapter in the CAO. However, those forest practices that are Class IV general should be regulated. These activities constitute a conversion from forestry to some other use. As such, buffers and wetland protections are appropriate.

### *Exemptions*

Your wetlands section should identify those activities in or near wetlands that are regulated and those that are exempt from regulation. Exemptions include activities that will have little or no environmental effect or are an emergency that threatens public health or safety. In the case of emergency response activities that affect wetlands and buffers, the responsible party should be required to obtain after-the-fact permits and to rectify impacts. Some jurisdictions place the exemptions or exceptions in a general exemptions section near the front of the CAO. However, some exemptions or exceptions may apply only to wetlands, so it may be more practical to have these specific exemptions in the wetlands section.

Exempt activities should be limited to those that will not have a significant impact on a wetland's structure and function (including its water, soil, or vegetation) and those that are expected to be very short term. Local governments should, however, also consider the cumulative impacts from exempted activities. They can result in a loss of wetland acreage and function that are not replaced through compensatory mitigation.

The scope, coverage, and applicability of a critical areas ordinance should capture the full range of activities that are detrimental to wetland functions. Therefore, exemptions should be supported by the scientific literature and be carefully crafted to minimize the potential for adverse impacts. However, a local government should not assume that an exemption is appropriate in the absence of science to refute the exemption. The language should clearly state whether a given activity is exempt from applicable standards in the code or whether it is exempt from needing a permit but still must comply with the code. Exemptions should be limited and construed narrowly.

For more information on this topic, please refer to Chapter 8 of *Wetlands in Washington State, Volume 2: Managing and Protecting Wetlands* (Ecology Publication #05-06-008, Olympia, WA, April 2005:

<https://fortress.wa.gov/ecy/publications/summarypages/0506008.html>).

The GMA, in [RCW 36.70a.030\(21\)](#), requires local governments to regulate wetlands that meet the GMA-required definition of “wetland” (see the definition of “wetland” in the previous section). This includes **Prior Converted Croplands (PCCs)** and **hydrologically isolated wetlands**, two types of wetlands that have been exempt from federal regulation at times. PCCs are wetlands that have been ditched and drained for active agricultural use before December 23, 1985. Isolated wetlands are those wetlands that have no surface hydrologic connection to waters of the United States. These wetlands must be regulated by your CAO. Please see <http://www.ecy.wa.gov/programs/sea/wetlands/isolated.html> for more information on how the state of Washington currently regulates isolated wetlands.

The scientific literature does not support exempting wetlands that are below a certain size. While we recognize an administrative desire to place size thresholds on wetlands that are to be regulated, you need to be aware that it is not possible to conclude from size alone what functions a particular wetland may be providing. Ecology has developed a strategy for exempting small wetlands when additional criteria are considered. This language is present in the sample ordinance. **However, impacts to small wetlands are NOT exempt from the requirement to provide compensatory mitigation for those impacts.** If an in-lieu fee (ILF) program or a mitigation bank is available in your area (see page 15), these mitigation alternatives can help prevent a net loss of wetland function from impacts to small wetlands in your jurisdiction.

Exceptions are typically addressed in a CAO in the context of reasonable use of property. For more information about this regulatory tool, see Section VII of the *Critical Areas Assistance Handbook* published by the Washington State Department of Commerce: <http://www.commerce.wa.gov/Documents/GMS-Critical-Areas-Assist-Handbook.pdf> . You should keep in mind that the Shoreline Management Act does not allow reasonable

use exceptions, providing instead a variance pathway to afford regulatory relief. **If you decide to incorporate your CAO into your SMP when the latter document is updated, you will need to address this potential inconsistency.**

### *Forest Practices*

Class I, II, and III forest practices should be exempted from the wetlands section of your CAO. These activities are regulated through RCW 76.09, the Forest Practices Act.

### *Agricultural Activities*

In 2011 the Washington Legislature created the Voluntary Stewardship Program (VSP) as an alternative for meeting GMA requirements related to protecting critical areas and agricultural lands. In 2015 the state provided funding for participating counties to begin the VSP planning process. For more information on this program, see <http://www.scc.wa.gov/voluntary-stewardship/>.

For the GMA update cycle beginning 2015, some counties will begin addressing critical area issues related to agriculture through a VSP work plan.

If your jurisdiction is **not** in a participating county or not in a participating watershed, then you must review and revise your development regulations for protecting wetlands as they apply to agricultural activities (see [RCW 36.70A.710](#)).

If your jurisdiction is in a VSP watershed designated by a participating county, your GMA responsibilities to protect critical areas from agricultural activities in or near wetlands will be achieved through the VSP work plan.

However, it is important to keep in mind that federal and state regulations, such as the Clean Water Act and the State Water Pollution Control Act are still applicable in all jurisdictions regardless of participation or non-participation in the VSP. The VSP does not alter the responsibility of property owners to meet water quality standards, protect wetlands, and comply with state and federal environmental regulations.

Ecology recommends the following for non-VSP jurisdictions:

“Existing and ongoing agricultural activities” are often exempted from the provisions of a CAO. These activities should be clearly defined and should not include removing trees, diverting or impounding water, excavation, ditching, draining, culverting, filling, grading, or similar activities that introduce new adverse impacts to wetlands or other aquatic resources. Maintenance of agricultural ditches should be limited to removing sediment in existing ditches to a specified depth at date of last maintenance. Conversion of wetlands that are not currently in agricultural use to a new agricultural use should be subject to the same regulations that govern new development.

Ecology encourages the use of Best Management Practices (BMPs), farm conservation plans, and incentive-based programs to improve agricultural practices in and near wetlands. The goal of the BMPs should be to ensure that ongoing agricultural activities

minimize their effects on water quality, riparian ecology, salmonid populations, and wildlife habitat.

## Strategies for Protecting Wetlands from Impacts

### *Wetlands Inventory*

You may wish to pursue accurate identification and rating of all wetlands in your planning area based on the *Washington State Wetland Rating System for Western Washington: 2014 Update* (Washington State Department of Ecology Publication #14-06-29, Olympia, WA, October 2014) and the approved federal wetland delineation manual and applicable regional supplements. These documents can be downloaded at:

- <http://www.ecy.wa.gov/programs/sea/wetlands/ratingsystems/index.html> (rating systems)
- <http://www.ecy.wa.gov/programs/sea/wetlands/delineation.html> (delineation manual and supplements)

While this approach may initially be more labor intensive and expensive, such information will allow rapid review of development proposals and can help your jurisdiction prioritize areas for preservation or acquisition.

This approach is consistent with BAS. It can help with the development of a landscape-analysis approach to protecting wetlands in your jurisdiction. Landscape analysis for critical areas facilitates and informs long-range planning. The City of Aberdeen used this approach in their CAO update. (See Section XX.050.B in the sample ordinance.)

### *ABCs*

The most basic approach to protecting wetland functions and values can be summarized as the **A-B-C Approach, or Avoid-Buffer-Compensate**. This means that a CAO should contain language to ensure that:

1. Wetlands impacts are **avoided** to the extent practicable.
2. Wetlands are **buffered** to protect them from adjacent land-use impacts.
3. Unavoidable impacts are **compensated**, or replaced.

Your CAO should provide requirements on how to reduce the severity of impacts to wetlands. When an alteration to a wetland is proposed, impacts should be avoided, minimized, or compensated for in the following sequential order of preference:

1. Avoiding the impact altogether by not taking a certain action or parts of an action;

2. Minimizing impacts by limiting the degree or magnitude of the action and its implementation, by using appropriate technology, or by taking affirmative steps to avoid or reduce impacts;
3. Rectifying the impact by repairing, rehabilitating, or restoring the affected environment;
4. Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action;
5. Compensating for the impact by replacing, enhancing, or providing substitute resources or environments; and/or
6. Monitoring the impact and taking appropriate corrective measures.

### *Buffers*

Establishing standards for wetland buffers is usually the most challenging part of developing a CAO. However, developing a predictable, reasonable approach for establishing buffers that includes the best available science is not as difficult as it may seem.

The scientific literature is unequivocal that **buffers are necessary to protect wetland functions** and values. The literature consistently reports that the primary factors to evaluate in determining appropriate buffer widths are:

1. The wetland type and functions needing protection (buffers filter sediment, nutrients, or toxics; screen noise and light; provide forage, nesting, or resting habitat for wetland-dependent species; etc.).
2. The types of adjacent land use and their expected impacts.
3. The characteristics of the buffer area (slope, soils, vegetation).

The widths of buffers needed vary widely, depending on these three factors. For example, providing filtration of coarse sediment from residential development next to a low-quality wetland would require only a relatively flat buffer of dense grasses or forest/shrub vegetation in the range of 20 to 30 feet. However, providing forage and nesting habitat for common wetland-dependent species such as waterfowl, herons, or amphibians in a high-quality wetland adjacent to residential development would require a buffer vegetated with trees and shrubs in the range of 200 to 300 feet. This illustrates the necessity of using an approach to buffers that incorporates wetland type and functions (based on an appropriate rating system), types of land use, and the environmental characteristics of the existing buffer.

Your CAO should require buffers for activities that will impact wetland functions. Ecology's complete buffer recommendations are presented in Appendix 8-C of *Wetlands*

*in Washington State, Volume 2* (revised October 2014). We recommend using the tables shown in the sample ordinance.

Tables XX.1 and XX.3 are derived from the more-detailed tables in *Volume 2*. They are easy to use and are based on BAS. This approach provides the important balance of predictability and flexibility. Determination of buffer size is simply a matter of applying the results of the wetland rating system score to the buffer matrix, based on the wetland category and wildlife habitat score. It generally requires smaller buffers for those wetlands that do not have much wildlife use.

Table XX.1 requires the use of the minimizing measures in Table XX.2. These measures are intended to reduce the impacts of the adjacent land use on the wetland. If impacts are reduced, the size of the buffer required to protect the wetland's functions can be reduced. The buffer widths in Table XX.1 represent a 25% reduction in our recommended buffers in *Volume 2*.

Table XX.1 also requires the protection of a wildlife corridor between wetlands that score 5 or more habitat points and any other Priority Habitat. This requirement is particularly applicable in large or rural jurisdictions where species need to have access to other habitats to meet their life needs. A buffer is the usual means of providing this necessary habitat. However, if buffer reduction is allowed, we cannot ensure that these species will have adequate access to habitat without providing a connective corridor. In urban areas, the best solution is a landscape-based approach that takes into account actual species use and spatial arrangement and connectivity of habitats. Without such an approach, jurisdictions should use the guidance provided in the sample wetland chapter.

If your jurisdiction is small and urban, providing a wildlife corridor may not be an option. You should consult with Ecology wetland staff to determine whether using Tables XX.1 and XX.2 alone will provide adequate protection for your wetland functions.

Table XX.3 shows the buffer widths required if the minimizing measures in Table XX.2 are **not** implemented and if a wildlife corridor is **not** protected. These buffers are wider than those in Table XX.1, because the impacts to the wetland functions are potentially greater.

The buffer tables XX.1 and XX.3 do not consider land-use intensity in the buffer calculation, since it is presumed that most urban land uses will be high or moderate intensity. However, if your jurisdiction has an activity that can be considered low intensity, such as a passive recreation area or nature park with undeveloped trails, you may wish to prescribe a smaller buffer **for that area only**. The buffer for an area should be no less than 75% of the otherwise required buffer. Such a "low-intensity" buffer is not appropriate for residential, commercial, or industrial uses. Of course, if your jurisdiction includes rural land uses, you should consider using the buffer tables in Appendix 8-C of *Wetlands in Washington State, Volume 2* (revised October 2014).

Some wetland types listed in the buffer tables may not be present in your jurisdiction (e.g., coastal lagoons, bogs, interdunal wetlands, etc.). If you are certain that these wetlands do not occur within your jurisdiction and would not be introduced by future annexations, you may remove those wetland types from the buffer tables.

You may wish to adopt an even simpler approach to wetland buffers, one based only on wetland category. In this case, buffers must be large enough to protect the most-sensitive wetlands from the most-damaging land-use impacts. Please refer to Table 8C-1 of Appendix 8-C of *Wetlands in Washington State, Volume 2* (revised October 2014) for this example.

Ecology's buffer recommendations are based on a moderate-risk approach to protecting wetland functions. This means that there is a moderate risk that wetland functions will be impacted. Adopting smaller buffers represents a high-risk approach, and you need to be prepared to justify why such an approach is necessary and to offer alternative means of protecting wetland functions that help reduce the risk.

**Ecology's buffer recommendations are also based on the assumption that the buffer is well vegetated with native species appropriate to the ecoregion.** If the buffer does not consist of vegetation adequate to provide the necessary protection, then either the buffer area should be planted or the buffer width should be increased.

### *Buffer Averaging*

Local governments often wish to allow buffer widths to be varied in certain circumstances. This may be reasonable if your standard buffers are adequate. The width of buffers may be averaged if this will improve the protection of wetland functions, or if it is the only way to allow for reasonable use of a parcel.

We recommend that a request for buffer averaging include a wetland report. The report should be prepared by a qualified professional describing the current functions of the wetland and its buffer and the measures that will be taken to ensure that there is no loss of wetland function due to the buffer averaging. The width of the buffer at any given point after averaging should be no smaller than 75% of the standard buffer.

If you choose to adopt narrower buffer widths than those supported by BAS, then further reductions to the buffer width should not be allowed under any circumstances.

### *Mitigation*

Applicants are required by state and federal permitting agencies to show that they have followed mitigation sequencing and have first avoided and minimized impacts to wetlands wherever practicable. Your CAO should include the definition of mitigation sequencing and require applicants to demonstrate that they have applied avoidance and minimization. For more information and sample checklists, see <http://www.ecy.wa.gov/programs/sea/wetlands/avoidance.html>.

Unavoidable **impacts to wetlands should be offset by compensatory mitigation**. Your CAO should include standards for the type, location, amount, and timing of the mitigation. It should also include clear guidance on the design considerations and reporting requirements for mitigation plans.

Ecology's recommendations for the amount of mitigation (ratios) are based on wetland category, function, and special characteristics. Requiring a greater area for mitigation than the wetland area that will be impacted helps offset both the risk that compensatory mitigation will fail and the temporal loss of functions that may occur. We recommend using the ratio table shown in the sample ordinance. It is derived from the more-detailed tables in Part 1 of the joint agency guidance on mitigation: *Wetland Mitigation in Washington State, Parts 1 and 2* (Ecology Publications #06-06-011a & b, March 2006).

As an alternative to the mitigation ratios found in the joint guidance, Ecology has developed a credit-debit tool for calculating when a proposed wetland mitigation project adequately replaces the functions and values lost when wetlands are impacted. The tool is designed to provide guidance for both regulators and applicants during two stages of the mitigation process:

1. Estimating the functions and values lost when a wetland is altered (debits), and
2. Estimating the gain in functions and values that result from the mitigation (credits).

The Department of Ecology, however, does not require the use of this credit-debit method. It provides one method for determining the adequacy of compensatory wetland mitigation. It does not set any new regulatory requirements. The document and worksheets can be downloaded at:

<http://www.ecy.wa.gov/programs/sea/wetlands/mitigation/creditdebit/index.html>.

In 2008 the Corps and the EPA issued a rule governing compensatory mitigation. The rule establishes performance standards and criteria to improve the quality and success of compensatory mitigation, mitigation banks, and in-lieu fee programs. For more information on the federal rule, see:

[http://water.epa.gov/lawsregs/guidance/wetlands/wetlandsmitigation\\_index.cfm](http://water.epa.gov/lawsregs/guidance/wetlands/wetlandsmitigation_index.cfm).

By adopting mitigation standards based on the state and federal guidance and rules, you will be providing consistency for applicants who must also apply for state and federal permits.

### *Mitigation Alternatives*

Various options are available for mitigation, in addition to the traditional on-site concurrent option. These options include placing the mitigation away from the project site (off-site mitigation), building mitigation in advance of project impacts, and using third-party mitigation providers such as wetland banks and in-lieu-fee programs. Deciding which option should be used depends on what works best for the applicant and

for the environment. Some of these options may not be available in your area at this time. However, we recommend that your CAO allow these options. They can be effective and valuable tools in preventing a net loss of wetland functions.

Some project applicants may propose mitigation that is consistent with sound ecological principles but is located outside of your jurisdiction. You may wish to include language in your CAO that enables your government to allow such out-of-jurisdiction mitigation opportunities.

In addition to the following options, you might want to consider allowing transfer of development rights (TDR) as a tool for protecting wetlands. The Department of Commerce is working with four Puget Sound counties in a pilot TDR program. For more information, contact the Commerce planner for your jurisdiction or see: [Commerce Regional Assistance Teams](#).

### Mitigation Banking

A mitigation bank is a site where wetlands, streams, and/or other aquatic resource areas have been restored, established, enhanced, or (in certain circumstances) preserved for the purpose of providing compensation for unavoidable impacts to aquatic resources. A mitigation bank may be created by a government agency, corporation, nonprofit organization, or other entity. The bank sells its credits to permittees who are required to compensate for wetland impacts. Mitigation banks allow a permittee to simply write a check for their mitigation obligation. It is the bank owner who is responsible for the mitigation success. Mitigation banks require a formal agreement with the Corps, Ecology, and the local jurisdiction to be used for federal or state permits.

Ecology adopted the final Wetland Mitigation Banks Rule (WAC 173-700) in 2009. The purpose of the rule is to provide a framework for the certification, operation, and monitoring of wetland mitigation banks. To learn more about wetland banking and the rule, see Ecology's website at <http://www.ecy.wa.gov/programs/sea/wetlands/mitigation/banking/index.html>.

### In-Lieu Fee (ILF)

In this approach to mitigation, a permittee pays a fee to a third party in lieu of conducting project-specific mitigation or buying credits from a mitigation bank. ILF mitigation is used mainly to compensate for impacts to wetlands when better approaches to compensation are not available or practicable, or when the use of an ILF is in the best interest of the environment.

An ILF represents the expected costs to a third party of replacing the wetland functions lost or degraded as a result of the permittee's project. Fees are typically held in trust until sufficient funds have been collected to finance a mitigation project. Only a nonprofit organization such as a local land trust, private conservation group, or government agency with demonstrated competence in natural resource management may operate an ILF program. All ILF programs must be approved by the Corps to be used for Section 404

permits. To learn more about ILF programs, see Ecology's website at <http://www.ecy.wa.gov/mitigation/ilf.html>.

### Off-Site Mitigation

This refers to compensatory mitigation that is not located at or near the project that generates impacts to wetlands. Off-site mitigation is generally allowed when on-site mitigation is not practicable or environmentally preferable.

The 2008 federal rule on compensatory mitigation requires that some type of watershed approach be used in siting mitigation. Ecology, the Corps of Engineers, and EPA have developed guidance to help applicants select potential off-site mitigation sites. To download a copy of this guidance, *Selecting Wetland Mitigation Sites Using a Watershed Approach (Western Washington)* (Ecology Publication #09-06-032, December 2009), please see <https://fortress.wa.gov/ecy/publications/summarypages/0906032.html>.

### Advance Mitigation

When compensatory mitigation is implemented before, and in anticipation of, future **known** impacts to wetlands, it is referred to as "advance mitigation." Advance mitigation has been used mostly for large mitigation projects that are constructed in distinct phases where the unavoidable impacts to wetlands are known. Advance mitigation lets an applicant provide all of the compensation needed for the entire project affecting wetlands at one time, which may result in more favorable mitigation ratios.

Although similar to mitigation banking, advance mitigation is different in several ways. Most importantly, advance mitigation is used only to compensate for the permittee's specific project (or projects) with pre-identified impacts to wetlands. Wetland banks provide mitigation for unknown future impacts within a specific "service" area. The advance mitigation can be used only by the permittee. Advance mitigation may not be sold unless it is changed to a wetland bank. Ecology, WDFW, and the Corps have developed guidance to help applicants develop advance mitigation proposals. To download a copy of this guidance, *Interagency Regulatory Guide: Advance Permittee-Responsible Mitigation* (Ecology Publication #12-06-015, December 2012), please see <https://fortress.wa.gov/ecy/publications/SummaryPages/1206015.html>

## **Conclusion**

We hope you find this information helpful. If you have questions about this document or need additional assistance with the wetlands section of your critical areas ordinance update, please call Donna Bunten at (360) 407-7172 or [donna.bunten@ecy.wa.gov](mailto:donna.bunten@ecy.wa.gov).

You may also contact one of Ecology's regional wetland specialists. They are available to work with you during your update process. For example, they can offer presentations to elected officials and planning commissions. They can also provide technical assistance including help with wetland delineation, wetland rating, ordinary high water

mark determination, and project review. Please use the following link to find the wetland specialist for your area:

<http://www.ecy.wa.gov/programs/sea/wetlands/contacts.htm>.

For assistance with other aspects of your critical areas ordinance update, please contact the Department of Commerce at (360) 725-3000.

*This page is purposely left blank*

## **Appendix A - Sample Wetlands Chapter**

### **(Western Washington)**

*This page is purposely left blank*

## **Subchapter XX.XX Wetlands**

### **Sections:**

XX.010 Purpose  
XX.020 Identification and Rating  
XX.030 Regulated Activities  
XX.040 Exemptions and Allowed Uses in Wetlands  
XX.050 Wetland Buffers  
XX.060 Critical Area Reports  
XX.070 Compensatory Mitigation  
XX.080 Unauthorized Alterations and Enforcement

### **XX.010 Purpose**

The purposes of this Chapter are to:

- A. Recognize and protect the beneficial functions performed by many wetlands, which include, but are not limited to, providing food, breeding, nesting and/or rearing habitat for fish and wildlife; recharging and discharging ground water; contributing to stream flow during low flow periods; stabilizing stream banks and shorelines; storing storm and flood waters to reduce flooding and erosion; and improving water quality through biofiltration, adsorption, and retention and transformation of sediments, nutrients, and toxicants.
- B. Regulate land use to avoid adverse effects on wetlands and maintain the functions and values of wetlands throughout (name of jurisdiction).
- C. Establish review procedures for development proposals in and adjacent to wetlands.
  - 1. Compliance with the provisions of the Chapter does not constitute compliance with other federal, state, and local regulations and permit requirements that may be required (for example, Shoreline Substantial Development Permits, HPA permits, Army Corps of Engineers Section 404 permits, NPDES permits). The applicant is responsible for complying with these requirements, apart from the process established in this Chapter.

### **XX.020 Identification and Rating**

A. Identification and Delineation. Identification of wetlands and delineation of their boundaries pursuant to this Chapter shall be done in accordance with the approved federal wetland delineation manual and applicable regional supplement. All areas within the City meeting the wetland designation criteria in that procedure are hereby designated critical areas and are subject to the provisions of this Chapter. Wetland delineations are

valid for five years; after such date the City shall determine whether a revision or additional assessment is necessary.

B. Rating. Wetlands shall be rated according to the Washington Department of Ecology wetland rating system, as set forth in the *Washington State Wetland Rating System for Western Washington: 2014 Update* (Ecology Publication #14-06-029, or as revised and approved by Ecology), which contains the definitions and methods for determining whether the criteria below are met.

1. Category I. Category I wetlands are: (1) relatively undisturbed estuarine wetlands larger than 1 acre; (2) wetlands of high conservation value that are identified by scientists of the Washington Natural Heritage Program/DNR; (3) bogs; (4) mature and old-growth forested wetlands larger than 1 acre; (5) wetlands in coastal lagoons; (6) interdunal wetlands that score 8 or 9 habitat points and are larger than 1 acre; and (7) wetlands that perform many functions well (scoring 23 points or more). These wetlands: (1) represent unique or rare wetland types; (2) are more sensitive to disturbance than most wetlands; (3) are relatively undisturbed and contain ecological attributes that are impossible to replace within a human lifetime; or (4) provide a high level of functions.
2. Category II. Category II wetlands are: (1) estuarine wetlands smaller than 1 acre, or disturbed estuarine wetlands larger than 1 acre; (2) interdunal wetlands larger than 1 acre or those found in a mosaic of wetlands; or (3) wetlands with a moderately high level of functions (scoring between 20 and 22 points).
3. Category III. Category III wetlands are: (1) wetlands with a moderate level of functions (scoring between 16 and 19 points); (2) can often be adequately replaced with a well-planned mitigation project; and (3) interdunal wetlands between 0.1 and 1 acre. Wetlands scoring between 16 and 19 points generally have been disturbed in some ways and are often less diverse or more isolated from other natural resources in the landscape than Category II wetlands.
4. Category IV. Category IV wetlands have the lowest levels of functions (scoring fewer than 16 points) and are often heavily disturbed. These are wetlands that we should be able to replace, or in some cases to improve. However, experience has shown that replacement cannot be guaranteed in any specific case. These wetlands may provide some important functions, and should be protected to some degree.

C. Illegal modifications. Wetland rating categories shall not change due to illegal modifications made by the applicant or with the applicant's knowledge.

### **XX.030 Regulated Activities**

A. For any regulated activity, a critical areas report (see Chapter XX.060 of this Chapter) may be required to support the requested activity.

B. The following activities are regulated if they occur in a regulated wetland or its buffer:

1. The removal, excavation, grading, or dredging of soil, sand, gravel, minerals, organic matter, or material of any kind.
2. The dumping of, discharging of, or filling with any material.
3. The draining, flooding, or disturbing of the water level or water table.
4. Pile driving.
5. The placing of obstructions.
6. The construction, reconstruction, demolition, or expansion of any structure.
7. The destruction or alteration of wetland vegetation through clearing, harvesting, shading, intentional burning, or planting of vegetation that would alter the character of a regulated wetland.
8. "Class IV - General Forest Practices" under the authority of the "1992 Washington State Forest Practices Act Rules and Regulations," WAC 222-12-030, or as thereafter amended.
9. Activities that result in:
  - a. A significant change of water temperature.
  - b. A significant change of physical or chemical characteristics of the sources of water to the wetland.
  - c. A significant change in the quantity, timing, or duration of the water entering the wetland.
  - d. The introduction of pollutants.

C. Subdivisions. The subdivision and/or short subdivision of land in wetlands and associated buffers are subject to the following:

1. Land that is located wholly within a wetland or its buffer may not be subdivided.

2. Land that is located partially within a wetland or its buffer may be subdivided provided that an accessible and contiguous portion of each new lot is:
  - a. Located outside of the wetland and its buffer; and
  - b. Meets the minimum lot size requirements of Chapter XX.XX.

#### **XX.040 Exemptions and Allowed Uses in Wetlands**

A. The following wetlands may be exempt from the requirement to avoid impacts (Chapter XX.070.A.1), and they may be filled if the impacts are fully mitigated based on the remaining actions in Chapter XX.070.A.2 through 6. If available, impacts should be mitigated through the purchase of credits from an in-lieu fee program or mitigation bank, consistent with the terms and conditions of the program or bank. In order to verify the following conditions, a critical area report for wetlands meeting the requirements in Chapter XX.060 must be submitted.

1. All isolated Category IV wetlands less than 4,000 square feet that:
  - a. Are not associated with riparian areas or their buffers
  - b. Are not associated with shorelines of the state or their associated buffers
  - c. Are not part of a wetland mosaic
  - d. Do not score 5 or more points for habitat function based on the 2014 update to the *Washington State Wetland Rating System for Western Washington: 2014 Update* (Ecology Publication #14-06-029, or as revised and approved by Ecology)
  - e. Do not contain a Priority Habitat or a Priority Area<sup>1</sup> for a Priority Species identified by the Washington Department of Fish and Wildlife, do not contain federally listed species or their critical habitat, or species of local importance identified in Chapter XX.XX.
2. Wetlands less than 1,000 square feet that meet the above criteria and do not contain federally listed species or their critical habitat are exempt from the buffer provisions contained in this Chapter.

---

<sup>1</sup>See page 6 of “Priority Habitat and Species List,” Washington Department of Fish and Wildlife, 2008, Olympia, Washington. 177 pp.

B. Activities Allowed in Wetlands. The activities listed below are allowed in wetlands. These activities do not require submission of a critical area report, except where such activities result in a loss of the functions and values of a wetland or wetland buffer. These activities include:

1. Existing and ongoing agricultural activities, provided that they implement applicable Best Management Practices (BMPs) contained in the latest editions of the USDA Natural Resources Conservation Service (NRCS) Field Office Technical Guide (FOTG); or develop a farm conservation plan in coordination with the local conservation district. BMPs and/or farm plans should address potential impacts to wetlands from livestock, nutrient and farm chemicals, soil erosion and sediment control and agricultural drainage infrastructure. BMPs and/or farm plans should ensure that ongoing agricultural activities minimize their effects on water quality, riparian ecology, salmonid populations, and wildlife habitat.
2. Those activities and uses conducted pursuant to the Washington State Forest Practices Act and its rules and regulations, WAC 222-12-030, where state law specifically exempts local authority, except those developments requiring local approval for Class 4 – General Forest Practice Permits (conversions) as defined in RCW 76.09 and WAC 222-12.
3. Conservation or preservation of soil, water, vegetation, fish, shellfish, and/or other wildlife that does not entail changing the structure or functions of the existing wetland.
4. The harvesting of wild crops in a manner that is not injurious to natural reproduction of such crops and provided the harvesting does not require tilling of soil, planting of crops, chemical applications, or alteration of the wetland by changing existing topography, water conditions, or water sources.
5. Drilling for utilities/utility corridors under a wetland, with entrance/exit portals located completely outside of the wetland buffer, provided that the drilling does not interrupt the ground water connection to the wetland or percolation of surface water down through the soil column. Specific studies by a hydrologist are necessary to determine whether the ground water connection to the wetland or percolation of surface water down through the soil column will be disturbed.
6. Enhancement of a wetland through the removal of non-native invasive plant species. Removal of invasive plant species shall be restricted to hand removal unless permits from the appropriate regulatory agencies have been obtained for approved biological or chemical treatments. All removed plant material shall be taken away from the site and appropriately

disposed of. Plants that appear on the Washington State Noxious Weed Control Board list of noxious weeds must be handled and disposed of according to a noxious weed control plan appropriate to that species. Re-vegetation with appropriate native species at natural densities is allowed in conjunction with removal of invasive plant species.

7. Educational and scientific research activities.
8. Normal and routine maintenance and repair of any existing public or private facilities within an existing right-of-way, provided that the maintenance or repair does not expand the footprint of the facility or right-of-way.
9. Stormwater management facilities. A wetland or its buffer can be physically or hydrologically altered to meet the requirements of an LID, Runoff Treatment or Flow Control BMP if ALL of the following criteria are met:
  - a. The wetland is classified as a Category IV or a Category III wetland with a habitat score of 3-4 points, and
  - b. There will be “no net loss” of functions and values of the wetland, and
  - c. The wetland does not contain a breeding population of any native amphibian species, and
  - d. The hydrologic functions of the wetland can be improved as outlined in questions 3, 4, 5 of Chart 4 and questions 2, 3, 4 of Chart 5 in the “Guide for Selecting Mitigation Sites Using a Watershed Approach,” (available here: <http://www.ecy.wa.gov/biblio/0906032.html>); or the wetland is part of a priority restoration plan that achieves restoration goals identified in a Shoreline Master Program or other local or regional watershed plan, and
  - e. The wetland lies in the natural routing of the runoff, and the discharge follows the natural routing, and
  - f. All regulations regarding stormwater and wetland management are followed, including but not limited to local and state wetland and stormwater codes, manuals, and permits, and
  - g. **Modifications that alter the structure of a wetland or its soils will require permits. Existing functions and values that are lost would have to be compensated/replaced.**

Stormwater LID BMPs required as part of New and Redevelopment projects can be considered within wetlands and their buffers. However, these areas may contain features that render LID BMPs infeasible. A site-specific characterization is required to determine if an LID BMP is feasible at the project site.

## XX.050 Wetland Buffers

A. Buffer Requirements. The following buffer widths have been established in accordance with the best available science. They are based on the category of wetland and the habitat score as determined by a qualified wetland professional using the *Washington State Wetland Rating System for Western Washington: 2014 Update* (Ecology Publication #14-06-029, or as revised and approved by Ecology). The adjacent land use intensity is assumed to be high.

1. For wetlands that score 5 points or more for habitat function, the buffers in Table XX.1 can be used if both of the following criteria are met:

- A relatively undisturbed, vegetated corridor at least 100 feet wide is protected between the wetland and any other Priority Habitats as defined by the Washington State Department of Fish and Wildlife. The latest definitions of priority habitats and their locations are available on the WDFW web site at:  
<http://wdfw.wa.gov/hab/phshabs.htm> )

The corridor must be protected for the entire distance between the wetland and the Priority Habitat by some type of legal protection such as a conservation easement.

Presence or absence of a nearby habitat must be confirmed by a qualified biologist. If no option for providing a corridor is available, Table XX.1 may be used with the required measures in Table XX.2 alone.<sup>2</sup>

- The measures in Table XX.2 are implemented, where applicable, to minimize the impacts of the adjacent land uses.
2. For wetlands that score 3-4 habitat points, only the measures in Table XX.2 are required for the use of Table XX.1
  3. If an applicant chooses **not** to apply the mitigation measures in Table XX.2, or is unable to provide a protected corridor where available, then Table XX.3 **must** be used.

---

<sup>2</sup> See discussion in the Introduction, page 12 as to whether this applies in small urban jurisdictions.

4. The buffer widths in Table XX.1 and XX.3 assume that the buffer is vegetated with a native plant community appropriate for the ecoregion. If the existing buffer is unvegetated, sparsely vegetated, or vegetated with invasive species that do not perform needed functions, the buffer should either be planted to create the appropriate plant community or the buffer should be widened to ensure that adequate functions of the buffer are provided.

5. Increased Wetland Buffer Area Width. Buffer widths shall be increased on a case-by-case basis as determined by the Administrator when a larger buffer is necessary to protect wetland functions and values. This determination shall be supported by appropriate documentation showing that it is reasonably related to protection of the functions and values of the wetland. The documentation must include but not be limited to the following criteria:
  - a. The wetland is used by a state or federally listed plant or animal species or has essential or outstanding habitat for those species, or has unusual nesting or resting sites such as heron rookeries or raptor nesting trees; or
  - b. The adjacent land is susceptible to severe erosion, and erosion-control measures will not effectively prevent adverse wetland impacts; or
  - c. The adjacent land has minimal vegetative cover or slopes greater than 30 percent.
6. Buffer averaging to *improve wetland protection* may be permitted when **all** of the following conditions are met:
  - a. The wetland has significant differences in characteristics that affect its habitat functions, such as a wetland with a forested component adjacent to a degraded emergent component or a “dual-rated” wetland with a Category I area adjacent to a lower-rated area.
  - b. The buffer is increased adjacent to the higher-functioning area of habitat or more-sensitive portion of the wetland and decreased adjacent to the lower-functioning or less-sensitive portion as demonstrated by a critical areas report from a qualified wetland professional.
  - c. The total area of the buffer after averaging is equal to the area required without averaging.
  - d. The buffer at its narrowest point is never less than either  $\frac{3}{4}$  of the required width or 75 feet for Category I and II, 50 feet for Category III, and 25 feet for Category IV, whichever is greater.
7. Averaging to *allow reasonable use* of a parcel may be permitted when **all** of the following are met:
  - a. There are no feasible alternatives to the site design that could be accomplished without buffer averaging.

- b. The averaged buffer will not result in degradation of the wetland's functions and values as demonstrated by a critical areas report from a qualified wetland professional.
- c. The total buffer area after averaging is equal to the area required without averaging.
- d. The buffer at its narrowest point is never less than either  $\frac{3}{4}$  of the required width or 75 feet for Category I and II, 50 feet for Category III and 25 feet for Category IV, whichever is greater.

B. To facilitate long-range planning using a landscape approach, the Administrator may identify and pre-assess wetlands using the rating system and establish appropriate wetland buffer widths for such wetlands. The Administrator will prepare maps of wetlands that have been pre-assessed in this manner.

C. Measurement of Wetland Buffers. All buffers shall be measured perpendicular from the wetland boundary as surveyed in the field. The buffer for a wetland created, restored, or enhanced as compensation for approved wetland alterations shall be the same as the buffer required for the category of the created, restored, or enhanced wetland. Buffers must be fully vegetated in order to be included in buffer area calculations. Lawns, walkways, driveways, and other mowed or paved areas will not be considered buffers or included in buffer area calculations.

D. Buffers on Wetland Mitigation Sites. All wetland mitigation sites shall have buffers consistent with the buffer requirements of this Chapter. Buffers shall be based on the expected or target category of the proposed wetland mitigation site.

E. Buffer Maintenance. Except as otherwise specified or allowed in accordance with this Chapter, wetland buffers shall be retained in an undisturbed or enhanced condition. In the case of compensatory mitigation sites, removal of invasive non-native weeds is required for the duration of the mitigation bond (Section XX.070.J.2.a.x).

F. Impacts to Buffers. Requirements for the compensation for impacts to buffers are outlined in Section XX.070 of this Chapter.

G. Overlapping Critical Area Buffers. If buffers for two contiguous critical areas overlap (such as buffers for a stream and a wetland), the wider buffer applies.

H. Allowed Buffer Uses. The following uses may be allowed within a wetland buffer in accordance with the review procedures of this Chapter, provided they are not prohibited by any other applicable law and they are conducted in a manner so as to minimize impacts to the buffer and adjacent wetland:

- 1. Conservation or restoration activities aimed at protecting the soil, water, vegetation, or wildlife.

2. Passive recreation facilities designed and in accordance with an approved critical area report, including:
  - a. Walkways and trails, provided that those pathways are limited to minor crossings having no adverse impact on water quality. They should be generally parallel to the perimeter of the wetland, located only in the outer twenty-five percent (25%) of the wetland buffer area, and located to avoid removal of significant trees. They should be limited to pervious surfaces no more than five (5) feet in width for pedestrian use only. Raised boardwalks utilizing non-treated pilings may be acceptable.
  - b. Wildlife-viewing structures.
3. Educational and scientific research activities.
4. Normal and routine maintenance and repair of any existing public or private facilities within an existing right-of-way, provided that the maintenance or repair does not increase the footprint or use of the facility or right-of-way.
5. The harvesting of wild crops in a manner that is not injurious to natural reproduction of such crops and provided the harvesting does not require tilling of soil, planting of crops, chemical applications, or alteration of the wetland by changing existing topography, water conditions, or water sources.
6. Drilling for utilities/utility corridors under a buffer, with entrance/exit portals located completely outside of the wetland buffer boundary, provided that the drilling does not interrupt the ground water connection to the wetland or percolation of surface water down through the soil column. Specific studies by a hydrologist are necessary to determine whether the ground water connection to the wetland or percolation of surface water down through the soil column would be disturbed.
7. Enhancement of a wetland buffer through the removal of non-native invasive plant species. Removal of invasive plant species shall be restricted to hand removal. All removed plant material shall be taken away from the site and appropriately disposed of. Plants that appear on the Washington State Noxious Weed Control Board list of noxious weeds must be handled and disposed of according to a noxious weed control plan appropriate to that species. Revegetation with appropriate native species at natural densities is allowed in conjunction with removal of invasive plant species.

8. Repair and maintenance of non-conforming uses or structures, where legally established within the buffer, provided they do not increase the degree of nonconformity.

I. Signs and Fencing of Wetlands and Buffers:

1. Temporary markers. The outer perimeter of the wetland buffer and the clearing limits identified by an approved permit or authorization shall be marked in the field with temporary “clearing limits” fencing in such a way as to ensure that no unauthorized intrusion will occur. The marking is subject to inspection by the Administrator prior to the commencement of permitted activities. This temporary marking shall be maintained throughout construction and shall not be removed until permanent signs, if required, are in place.
2. Permanent signs. As a condition of any permit or authorization issued pursuant to this Chapter, the Administrator may require the applicant to install permanent signs along the boundary of a wetland or buffer.
  - a. Permanent signs shall be made of an enamel-coated metal face and attached to a metal post or another non-treated material of equal durability. Signs must be posted at an interval of one (1) every fifty (50) feet, or one (1) per lot if the lot is less than fifty (50) feet wide, and must be maintained by the property owner in perpetuity. The signs shall be worded as follows or with alternative language approved by the Administrator:

**Protected Wetland Area  
Do Not Disturb  
Contact [Local Jurisdiction]  
Regarding Uses, Restrictions, and Opportunities for Stewardship**

- b. The provisions of Subsection (a) may be modified as necessary to assure protection of sensitive features or wildlife.
3. Fencing
  - a. The applicant shall be required to install a permanent fence around the wetland or buffer when domestic grazing animals are present or may be introduced on site.
  - b. Fencing installed as part of a proposed activity or as required in this Subsection shall be designed so as to not interfere with species migration, including fish runs, and shall be constructed in a manner that minimizes impacts to the wetland and associated habitat.

## **XX.060 Critical Area Report for Wetlands**

A. If the Administrator determines that the site of a proposed development includes, is likely to include, or is adjacent to a wetland, a wetland report, prepared by a qualified professional, shall be required. The expense of preparing the wetland report shall be borne by the applicant.

B. Minimum Standards for Wetland Reports. The written report and the accompanying plan sheets shall contain the following information, at a minimum:

1. The written report shall include at a minimum:
  - a. The name and contact information of the applicant; the name, qualifications, and contact information for the primary author(s) of the wetland critical area report; a description of the proposal; identification of all the local, state, and/or federal wetland-related permit(s) required for the project; and a vicinity map for the project.
  - b. A statement specifying the accuracy of the report and all assumptions made and relied upon.
  - c. Documentation of any fieldwork performed on the site, including field data sheets for delineations, rating system forms, baseline hydrologic data, etc.
  - d. A description of the methodologies used to conduct the wetland delineations, wetland ratings, or impact analyses, including references.
  - e. Identification and characterization of all critical areas, wetlands, water bodies, shorelines, floodplains, and buffers on or adjacent to the proposed project area. For areas off site of the project site, estimate conditions within 300 feet of the project boundaries using the best available information.
  - f. For each wetland identified on site and within 300 feet of the project boundary, provide: the wetland rating, including a description of and score for each function, per *Wetland Ratings* (Section XX.020.B) of this Chapter; required buffers; hydrogeomorphic classification; wetland acreage based on a professional survey from the field delineation (acreages for on-site portion or estimate entire wetland area including off-site portions); Cowardin classification of vegetation communities; habitat elements; soil conditions based on site assessment and/or soil survey information; and to the extent possible, hydrologic information such as location and condition of inlets/outlets (if they can be legally accessed), estimated water depths within the wetland, and estimated hydroperiod patterns based on visual cues (e.g.,

algal mats, drift lines, flood debris, etc.). Provide acreage estimates, classifications, and ratings based on entire wetland complexes, not only the portion present on the proposed project site.

- g. A description of the proposed actions, including an estimation of acreages of impacts to wetlands and buffers based on the field delineation and survey and an analysis of site development alternatives, including a no-development alternative.
  - h. An assessment of the probable cumulative impacts to the wetlands and buffers resulting from the proposed development.
  - i. A description of reasonable efforts made to apply mitigation sequencing pursuant to *Mitigation Sequencing* (Chapter XX.070.A) to avoid, minimize, and mitigate impacts to critical areas.
  - j. A discussion of measures, including avoidance, minimization, and compensation, proposed to preserve existing wetlands and restore any wetlands that were degraded prior to the current proposed land-use activity.
  - k. A conservation strategy for habitat and native vegetation that addresses methods to protect and enhance on-site habitat and wetland functions.
  - l. An evaluation of the functions of the wetland and its buffer. Include references for the method used and data sheets.
2. A copy of the site plan sheet(s) for the project must be included with the written report and must include, at a minimum:
- a. Maps (to scale) depicting delineated and surveyed wetland and required buffers on site, including buffers for off-site critical areas that extend onto the project site; the development proposal; other critical areas; grading and clearing limits; and areas of proposed impacts to wetlands and/or buffers (include square footage estimates).
  - b. A depiction of the proposed stormwater management facilities and outlets (to scale) for the development, including estimated areas of intrusion into the buffers of any critical areas. The written report shall contain a discussion of the potential impacts to the wetland(s) associated with anticipated hydroperiod alterations from the project.

## **XX.070 Compensatory Mitigation.**

A. Mitigation Sequencing. Before impacting any wetland or its buffer, an applicant shall demonstrate that the following actions have been taken. Actions are listed in the order of preference:

1. Avoid the impact altogether by not taking a certain action or parts of an action.
2. Minimize impacts by limiting the degree or magnitude of the action and its implementation, by using appropriate technology, or by taking affirmative steps to avoid or reduce impacts.
3. Rectify the impact by repairing, rehabilitating, or restoring the affected environment.
4. Reduce or eliminate the impact over time by preservation and maintenance operations.
5. Compensate for the impact by replacing, enhancing, or providing substitute resources or environments.
6. Monitor the required compensation and take remedial or corrective measures when necessary.

### **B. Requirements for Compensatory Mitigation:**

1. Compensatory mitigation for alterations to wetlands shall be used only for impacts that cannot be avoided or minimized and shall achieve equivalent or greater biologic functions. Compensatory mitigation plans shall be consistent with *Wetland Mitigation in Washington State—Part 2: Developing Mitigation Plans—Version 1*, (Ecology Publication #06-06-011b, Olympia, WA, March 2006, or as revised), and *Selecting Wetland Mitigation Sites Using a Watershed Approach (Western Washington)* (Publication #09-06-32, Olympia, WA, December 2009).
2. Mitigation ratios shall be consistent with Subsection H of this Chapter.
3. Mitigation requirements may also be determined using the credit/debit tool described in *Calculating Credits and Debits for Compensatory Mitigation in Wetlands of Western Washington: Final Report* (Ecology Publication #10-06-011, Olympia, WA, March 2012, or as revised) consistent with subsection H of this Chapter.

C. Compensating for Lost or Affected Functions. Compensatory mitigation shall address the functions affected by the proposed project, with an intention to achieve functional equivalency or improvement of functions. The goal shall be for the

compensatory mitigation to provide similar wetland functions as those lost, except when either:

1. The lost wetland provides minimal functions, and the proposed compensatory mitigation action(s) will provide equal or greater functions or will provide functions shown to be limiting within a watershed through a formal Washington state watershed assessment plan or protocol; or
2. Out-of-kind replacement of wetland type or functions will best meet watershed goals formally identified by the City, such as replacement of historically diminished wetland types.

D. Approaches to Compensatory Mitigation. Mitigation for lost or diminished wetland and buffer functions shall rely on the approaches listed below.

1. Wetland mitigation banks. Credits from a certified wetland mitigation bank may be used to compensate for impacts located within the service area specified in the mitigation bank instrument. Use of credits from a wetland mitigation bank certified under Chapter 173-700 WAC is allowed if:
  - a. The approval authority determines that it would provide appropriate compensation for the proposed impacts; and
  - b. The impact site is located in the service area of the bank.
  - c. The proposed use of credits is consistent with the terms and conditions of the certified mitigation bank instrument.
  - d. Replacement ratios for projects using bank credits is consistent with replacement ratios specified in the certified mitigation bank instrument.
2. In-Lieu Fee Mitigation: Credits from an approved in-lieu-fee program may be used when all of the following apply:
  - a. The approval authority determines that it would provide environmentally appropriate compensation for the proposed impacts.
  - b. The proposed use of credits is consistent with the terms and conditions of the approved in-lieu-fee program instrument.
  - c. Projects using in-lieu-fee credits shall have debits associated with the proposed impacts calculated by the applicant's qualified wetland professional using the credit assessment method specified in the approved instrument for the in-lieu-fee program.

- d. The impacts are located within the service area specified in the approved in-lieu-fee instrument.
3. Permittee-responsible mitigation. In this situation, the permittee performs the mitigation after the permit is issued and is ultimately responsible for implementation and success of the mitigation. Permittee-responsible mitigation may occur at the site of the permitted impacts or at an off-site location within the same watershed. Permittee-responsible mitigation shall be used only if the applicant's qualified wetland professional demonstrates to the approval authority's satisfaction that the proposed approach is ecologically preferable to use of a bank or ILF program, consistent with the criteria in this section.

E. Types of Compensatory Mitigation. Mitigation for lost or diminished wetland and buffer functions shall rely on a type listed below in order of preference. A lower-preference form of mitigation shall be used only if the applicant's qualified wetland professional demonstrates to the approval authority's satisfaction that all higher-ranked types of mitigation are not viable, consistent with the criteria in this section.

1. Restoration: The manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning natural or historic functions to a former or degraded wetland. For the purpose of tracking net gains in wetland acres, restoration is divided into:
  - a. Re-establishment: The manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning natural or historic functions to a former wetland. Re-establishment results in a gain in wetland acres (and functions). Activities could include removing fill material, plugging ditches, or breaking drain tiles.
  - b. Rehabilitation: The manipulation of the physical, chemical, or biological characteristics of a site with the goal of repairing natural or historic functions of a degraded wetland. Rehabilitation results in a gain in wetland function but does not result in a gain in wetland acres. Activities could involve breaching a dike to reconnect wetlands to a floodplain or return tidal influence to a wetland.
2. Establishment (Creation): The manipulation of the physical, chemical, or biological characteristics of a site to develop a wetland on an upland or deepwater site where a wetland did not previously exist. Establishment results in a gain in wetland acres. Activities typically involve excavation of upland soils to elevations that will produce a wetland hydroperiod, create hydric soils, and support the growth of hydrophytic plant species.
  - a. If a site is not available for wetland restoration to compensate for expected wetland and/or buffer impacts, the approval authority may

authorize creation of a wetland and buffer upon demonstration by the applicant's qualified wetland professional that:

- i. The hydrology and soil conditions at the proposed mitigation site are conducive for sustaining the proposed wetland and that creation of a wetland at the site will not likely cause hydrologic problems elsewhere;
  - ii. Adjacent land uses and site conditions do not jeopardize the viability of the proposed wetland and buffer (e.g., due to the presence of invasive plants or noxious weeds, stormwater runoff, noise, light, or other impacts); and
  - iii. The proposed wetland and buffer will eventually be self-sustaining with little or no long-term maintenance.
3. **Enhancement.** The manipulation of the physical, chemical, or biological characteristics of a wetland site to heighten, intensify, or improve specific function(s) or to change the growth stage or composition of the vegetation present. Enhancement is undertaken for specified purposes such as water quality improvement, flood water retention, or wildlife habitat. Enhancement results in a change in some wetland functions and can lead to a decline in other wetland functions, but does not result in a gain in wetland acres. Activities typically consist of planting vegetation, controlling non-native or invasive species, modifying site elevations or the proportion of open water to influence hydroperiods, or some combination of these activities. Applicants proposing to enhance wetlands or associated buffers shall demonstrate how the proposed enhancement will increase the wetland's/buffer's functions, how this increase in function will adequately compensate for the impacts, and how existing wetland functions at the mitigation site will be protected.
4. **Protection/Maintenance (Preservation).** Removing a threat to, or preventing the decline of, wetland conditions by an action in or near a wetland. This includes the purchase of land or easements, or repairing water control structures or fences. This term also includes activities commonly associated with the term *preservation*. Preservation does not result in a gain of wetland acres. Permanent protection of a Category I or II wetland and associated buffer at risk of degradation can be used only if:
  - a. The approval authority determines that the proposed preservation is the best mitigation option;
  - b. The proposed preservation site is under threat of undesirable ecological change due to permitted, planned, or likely actions that will not be adequately mitigated under existing regulations;

- c. The area proposed for preservation is of high quality or critical for the health of the watershed or basin due to its location. Some of the following features may be indicative of high-quality sites:
  - i. Category I or II wetland rating (using the wetland rating system for western Washington)
  - ii. Rare or irreplaceable wetland type (for example, bogs, mature forested wetlands, estuarine wetlands) or aquatic habitat that is rare or a limited resource in the area;
  - iii. The presence of habitat for priority or locally important wildlife species; or also list has provides biological and/or hydrological connectivity;
  - iv. Provides biological and/or hydrological connectivity;
  - v. Priority sites in an adopted watershed plan.
- d. Permanent preservation of the wetland and buffer will be provided through a conservation easement or tract held by an appropriate natural land resource manager, such as a land trust.
- e. The approval authority may approve other legal and administrative mechanisms in lieu of a conservation easement if it determines they are adequate to protect the site.
- f. Ratios for preservation in combination with other forms of mitigation generally range from 10:1 to 20:1, as determined on a case-by-case basis, depending on the quality of the wetlands being impacted and the quality of the wetlands being preserved. Ratios for preservation as the sole means of mitigation generally start at 20:1.

F. Location of Compensatory Mitigation. Compensatory mitigation actions shall generally be conducted within the same sub-drainage basin and on the site of the alteration except when the applicant can demonstrate that off-site mitigation is ecologically preferable. The following criteria will be evaluated when determining whether the proposal is ecologically preferable. When considering off-site mitigation, preference should be given to using alternative mitigation, such as a mitigation bank, an in-lieu-fee program, or advance mitigation.

- 1. There are no reasonable opportunities on site or within the sub-drainage basin (e.g., on-site options would require elimination of high-functioning upland habitat), or opportunities on site or within the sub-drainage basin do not have a high likelihood of success based on a determination of the capacity of the site to compensate for the impacts. Considerations should

include: anticipated replacement ratios for wetland mitigation, buffer conditions and required widths, available water to maintain anticipated hydrogeomorphic classes of wetlands when restored, proposed flood storage capacity, and potential to mitigate riparian fish and wildlife impacts (such as connectivity);

2. On-site mitigation would require elimination of high-quality upland habitat.
3. Off-site mitigation has a greater likelihood of providing equal or improved wetland functions than the altered wetland.
4. Off-site locations shall be in the same sub-drainage basin unless:
  - a. Established watershed goals for water quality, flood storage or conveyance, habitat, or other wetland functions have been established by the City and strongly justify location of mitigation at another site; or
  - b. Credits from a state-certified wetland mitigation bank are used as compensation, and the use of credits is consistent with the terms of the certified bank instrument;
  - c. Fees are paid to an approved in-lieu-fee program to compensate for the impacts.
5. The design for the compensatory mitigation project needs to be appropriate for its location (i.e., position in the landscape). Therefore, compensatory mitigation should not result in the creation, restoration, or enhancement of an atypical wetland.

G. Timing of Compensatory Mitigation. It is preferred that compensatory mitigation projects be completed prior to activities that will impact wetlands. At the least, compensatory mitigation shall be completed immediately following disturbance and prior to use or occupancy of the action or development. Construction of mitigation projects shall be timed to reduce impacts to existing fisheries, wildlife, and flora.

1. The Administrator may authorize a one-time temporary delay in completing construction or installation of the compensatory mitigation when the applicant provides a written explanation from a qualified wetland professional as to the rationale for the delay. An appropriate rationale would include identification of the environmental conditions that could produce a high probability of failure or significant construction difficulties (e.g., project delay lapses past a fisheries window, or installing plants should be delayed until the dormant season to ensure greater survival of installed materials). The delay shall not create or perpetuate hazardous conditions or environmental damage or degradation, and the

delay shall not be injurious to the health, safety, or general welfare of the public. The request for the temporary delay must include a written justification that documents the environmental constraints that preclude implementation of the compensatory mitigation plan. The justification must be verified and approved by the City.

#### H. Wetland Mitigation Ratios<sup>3</sup>:

| Category and Type of Wetland              | Creation or Re-establishment | Rehabilitation | Enhancement  |
|-------------------------------------------|------------------------------|----------------|--------------|
| Category I:<br>Bog, Natural Heritage site | Not considered possible      | Case by case   | Case by case |
| Category I:<br>Mature Forested            | 6:1                          | 12:1           | 24:1         |
| Category I:<br>Based on functions         | 4:1                          | 8:1            | 16:1         |
| Category II                               | 3:1                          | 6:1            | 12:1         |
| Category III                              | 2:1                          | 4:1            | 8:1          |
| Category IV                               | 1.5:1                        | 3:1            | 6:1          |

I. Credit/Debit Method. To more fully protect functions and values, and as an alternative to the mitigation ratios found in the joint guidance *Wetland Mitigation in Washington State Parts I and II* (Ecology Publication #06-06-011a-b, Olympia, WA, March 2006), the administrator may allow mitigation based on the “credit/debit” method developed by the Department of Ecology in *Calculating Credits and Debits for Compensatory Mitigation in Wetlands of Western Washington: Final Report*, (Ecology Publication #10-06-011, Olympia, WA, March 2012, or as revised).

---

<sup>3</sup> Ratios for rehabilitation and enhancement may be reduced when combined with 1:1 replacement through creation or re-establishment. See Table 1a, *Wetland Mitigation in Washington State – Part 1: Agency Policies and Guidance –Version 1*, (Ecology Publication #06-06-011a, Olympia, WA, March 2006 or as revised). See also Paragraph D.4 for more information on using preservation as compensation.

J. Compensatory Mitigation Plan. When a project involves wetland and/or buffer impacts, a compensatory mitigation plan prepared by a qualified professional shall be required, meeting the following minimum standards:

1. Wetland Critical Area Report. A critical area report for wetlands must accompany or be included in the compensatory mitigation plan and include the minimum parameters described in *Minimum Standards for Wetland Reports* (Section XX.060.B) of this Chapter.
2. Compensatory Mitigation Report. The report must include a written report and plan sheets that contain, at a minimum, the following elements. Full guidance can be found in *Wetland Mitigation in Washington State– Part 2: Developing Mitigation Plans (Version 1)* (Ecology Publication #06-06-011b, Olympia, WA, March 2006 or as revised).
  - a. The written report must contain, at a minimum:
    - i. The name and contact information of the applicant; the name, qualifications, and contact information for the primary author(s) of the compensatory mitigation report; a description of the proposal; a summary of the impacts and proposed compensation concept; identification of all the local, state, and/or federal wetland-related permit(s) required for the project; and a vicinity map for the project.
    - ii. Description of how the project design has been modified to avoid, minimize, or reduce adverse impacts to wetlands.
    - iii. Description of the existing wetland and buffer areas proposed to be altered. Include acreage (or square footage), water regime, vegetation, soils, landscape position, surrounding land uses, and functions. Also describe impacts in terms of acreage by Cowardin classification, hydrogeomorphic classification, and wetland rating, based on *Wetland Ratings* (Section XX.XX) of this Chapter.
    - iv. Description of the compensatory mitigation site, including location and rationale for selection. Include an assessment of existing conditions: acreage (or square footage) of wetlands and uplands, water regime, sources of water, vegetation, soils, landscape position, surrounding land uses, and functions. Estimate future conditions in this location if the compensation actions are NOT undertaken (i.e., how would this site progress through natural succession?).
    - v. Surface and subsurface hydrologic conditions, including an analysis of existing and proposed hydrologic regimes for enhanced, created, or restored compensatory mitigation areas.

Include illustrations of how data for existing hydrologic conditions were used to determine the estimates of future hydrologic conditions

- vi. A description of the proposed actions for compensation of wetland and upland areas affected by the project. Include overall goals of the proposed mitigation, including a description of the targeted functions, hydrogeomorphic classification, and categories of wetlands.
  - vii. A description of the proposed mitigation construction activities and timing of activities.
  - viii. Performance standards (measurable standards for years post-installation) for upland and wetland communities, a monitoring schedule, and a maintenance schedule and actions proposed by year.
  - ix. A discussion of ongoing management practices that will protect wetlands after the development project has been implemented, including proposed monitoring and maintenance programs (for remaining wetlands and compensatory mitigation wetlands).
  - x. A bond estimate for the entire compensatory mitigation project, including the following elements: site preparation, plant materials, construction materials, installation oversight, maintenance twice per year for up to five (5) years, annual monitoring field work and reporting, and contingency actions for a maximum of the total required number of years for monitoring.
  - xi. Proof of establishment of Notice on Title for the wetlands and buffers on the project site, including the compensatory mitigation areas.
- b. The scaled plan sheets for the compensatory mitigation must contain, at a minimum:
- i. Surveyed edges of the existing wetland and buffers, proposed areas of wetland and/or buffer impacts, location of proposed wetland and/or buffer compensation actions.
  - ii. Existing topography, ground-proofed, at two-foot contour intervals in the zone of the proposed compensation actions if any grading activity is proposed in the compensation area(s). Also include existing cross-sections (estimated one-foot intervals) of wetland areas on the development site that are proposed to be altered and for the proposed areas of wetland or buffer compensation.

- iii. Conditions expected from the proposed actions on site, including future hydrogeomorphic types, vegetation community types by dominant species (wetland and upland), and future water regimes.
- iv. Required wetland buffers for existing wetlands and proposed compensation areas. Also identify any zones where buffers are proposed to be reduced or enlarged outside of the standards identified in this Chapter.
- v. A planting plan for the compensation area, including all species by proposed community type and water regime, size and type of plant material to be installed, spacing of plants, typical clustering patterns, total number of each species by community type, and timing of installation.

K. Buffer Mitigation Ratios. Impacts to buffers shall be mitigated at a minimum 1:1 ratio. Compensatory buffer mitigation shall replace those buffer functions lost from development.

L. Protection of the Mitigation Site. The mitigation area and any associated buffer shall be located in a critical area tract or a conservation easement consistent with Chapter XX.XX.

M. Monitoring. Mitigation monitoring shall be required for a period necessary to establish that performance standards have been met, but not for a period less than five years. If a scrub-shrub or forested vegetation community is proposed, monitoring may be required for ten years or more. The project mitigation plan shall include monitoring elements that ensure certainty of success for the project's natural resource values and functions. If the mitigation goals are not obtained within the initial five-year period, the applicant remains responsible for restoration of the natural resource values and functions until the mitigation goals agreed to in the mitigation plan are achieved.

N. Advance Mitigation. Mitigation for projects with pre-identified impacts to wetlands may be constructed in advance of the impacts if the mitigation is implemented according to federal rules, state policy on advance mitigation, and state water quality regulations consistent with *Interagency Regulatory Guide: Advance Permittee-Responsible Mitigation* (Ecology Publication #12-06-015, Olympia, WA, December 2012).

O. Alternative Mitigation Plans. The Administrator may approve alternative wetland mitigation plans that are based on best available science, such as priority restoration plans that achieve restoration goals identified in the SMP. Alternative mitigation proposals must provide an equivalent or better level of protection of wetland functions and values than would be provided by the strict application of this chapter.

The Administrator shall consider the following for approval of an alternative mitigation proposal:

1. The proposal uses a watershed approach consistent with *Selecting Wetland Mitigation Sites Using a Watershed Approach (Western Washington)* (Ecology Publication #09-06-32, Olympia, WA, December 2009).
2. Creation or enhancement of a larger system of natural areas and open space is preferable to the preservation of many individual habitat areas.
3. Mitigation according to Section E is not feasible due to site constraints such as parcel size, stream type, wetland category, or geologic hazards.
4. There is clear potential for success of the proposed mitigation at the proposed mitigation site.
5. The plan shall contain clear and measurable standards for achieving compliance with the specific provisions of the plan. A monitoring plan shall, at a minimum, meet the provisions in Section J.
6. The plan shall be reviewed and approved as part of overall approval of the proposed use.
7. A wetland of a different type may be justified based on regional needs or functions and values; the replacement ratios may not be reduced or eliminated unless the reduction results in a preferred environmental alternative.
8. Mitigation guarantees shall meet the minimum requirements as outlined in Section J.2.a.viii.
9. Qualified professionals in each of the critical areas addressed shall prepare the plan.
10. The City may consult with agencies with expertise and jurisdiction over the critical areas during the review to assist with analysis and identification of appropriate performance measures that adequately safeguard critical areas.

## **XX.080 Unauthorized Alterations and Enforcement**

A. When a wetland or its buffer has been altered in violation of this Chapter, all ongoing development work shall stop, and the critical area shall be restored. The City shall have the authority to issue a “stop-work” order to cease all ongoing development work and order restoration, rehabilitation, or replacement measures at the owner’s or other responsible party’s expense to compensate for violation of provisions of this Chapter.

B. Requirement for Restoration Plan. All development work shall remain stopped until a restoration plan is prepared and approved by the City. Such a plan shall be prepared by a qualified professional using the currently accepted scientific principles and shall describe how the actions proposed meet the minimum requirements described in Subsection C below. The Administrator shall, at the applicant or other responsible party's expense, seek expert advice in determining the adequacy of the plan. Inadequate plans shall be returned to the applicant or other responsible party for revision and re-submittal.

C. Minimum Performance Standards for Restoration. The following minimum performance standards shall be met for the restoration of a wetland, provided that if the applicant or other responsible party can demonstrate that greater functions and habitat values can be obtained, these standards may be modified:

1. The historic structure, functions, and values of the affected wetland shall be restored, including water quality and habitat functions.
2. The historic soil types and configuration shall be restored to the extent practicable.
3. The wetland and buffers shall be replanted with native vegetation that replicates the vegetation historically found on the site in species types, sizes, and densities. The historic functions and values should be replicated at the location of the alteration.
4. Information demonstrating compliance with other applicable provisions of this Chapter shall be submitted to the Administrator.

D. Site Investigations. The Administrator is authorized to make site inspections and take such actions as are necessary to enforce this Chapter. The Administrator shall present proper credentials and make a reasonable effort to contact any property owner before entering onto private property.

E. Penalties. Any person, party, firm, corporation, or other legal entity convicted of violating any of the provisions of this Chapter shall be guilty of a misdemeanor.

1. Each day or portion of a day during which a violation of this Chapter is committed or continued shall constitute a separate offense. Any development carried out contrary to the provisions of this Chapter shall constitute a public nuisance and may be enjoined as provided by the statutes of the state of Washington. The City may levy civil penalties against any person, party, firm, corporation, or other legal entity for violation of any of the provisions of this Chapter. The civil penalty shall be assessed at a maximum rate of \$XX dollars per day per violation.
2. If the wetland affected cannot be restored, monies collected as penalties shall be deposited in a dedicated account for the preservation or

restoration of landscape processes and functions in the watershed in which the affected wetland is located. The City may coordinate its preservation or restoration activities with other cities in the watershed to optimize the effectiveness of the restoration action.

## **Appendix B - Wetland Definitions**

### **(Western Washington)**

*This page is purposely left blank*

## Appendix B – Wetland Definitions

**Agricultural Activities, Existing and Ongoing** – Those activities conducted on lands defined in RCW 84.34.020(2), and those activities involved in the production of crops and livestock, including but not limited to operation, maintenance and conservation measures of farm and stock ponds or drainage ditches, irrigation systems, changes between agricultural activities, and normal operation, maintenance or repair of existing serviceable structures, facilities or improved areas. Activities which bring an area into agricultural use are not part of an ongoing activity. An operation ceases to be ongoing when the area in which it was conducted is proposed for conversion to a nonagricultural use or has lain idle for a period of longer than five years, unless the idle land is registered in a federal or state soils conversation program.

**Alteration** – Any human-induced change in an existing condition of a critical area or its buffer. Alterations include, but are not limited to, grading, filling, channelizing, dredging, clearing of vegetation, construction, compaction, excavation, or any other activity that changes the character of the critical area.

**Best Available Science** – Current scientific information used in the process to designate, protect, or restore critical areas; that is, derived from a valid scientific process as defined by WAC 365-195-900 through 925.

**Best Management Practices (BMPs)** – Conservation practices or systems of practices and management measures that:

- (a) Control soil loss and reduce water quality degradation caused by high concentrations of nutrients, animal waste, toxics, or sediment;
- (b) Minimize adverse impacts to surface water and ground water flow and circulation patterns and to the chemical, physical, and biological characteristics of wetlands;
- (c) Protect trees, vegetation, and soils designated to be retained during and following site construction and use native plant species appropriate to the site for re-vegetation of disturbed areas; and
- (d) Provide standards for proper use of chemical herbicides within critical areas.

**Bog** – A low-nutrient, acidic wetland with organic soils and characteristic bog plants, as described in *Washington State Wetland Rating System for Western Washington: 2014 Update* (Washington State Department of Ecology Publication #14-06-29, Olympia, WA, October 2014).

**Buffer or Buffer Zone** – The area contiguous with a critical area that maintains the functions and/or structural stability of the critical area.

**Coastal Lagoon** – A shallow body of water partly or completely separated from the sea by a barrier beach that receives periodic influxes of salt water, as described in *Washington State Wetland Rating System for Western Washington: 2014 Update* (Washington State Department of Ecology Publication #14-06-29, Olympia, WA, October 2014).

**Critical Areas** – Critical areas include any of the following areas or ecosystems: critical aquifer recharge areas, fish and wildlife habitat conservation areas, geologically hazardous areas, frequently flooded areas, and wetlands, as defined in RCW 36.70A and this Chapter.

**Creation** – The manipulation of the physical, chemical, or biological characteristics to develop a wetland on an upland or deepwater site where a wetland did not previously exist. Creation results in a gain in wetland acreage and function. A typical action is the excavation of upland soils to elevations that will produce a wetland *hydroperiod* and hydric soils, and support the growth of hydrophytic plant species.

**Cumulative Impacts or Effects** – The combined, incremental effects of human activity on ecological or critical area functions and values. Cumulative impacts result when the effects of an action are added to or interact with the effects of other actions in a particular place and within a particular time. It is the combination of these effects, and any resulting environmental degradation, that should be the focus of cumulative impact analysis and changes to policies and permitting decisions.

**Development** – A land use consisting of the construction or exterior alteration of structures; grading, dredging, drilling, or dumping; filling; removal of sand, gravel, or minerals; bulk heading; driving of pilings; or any project of a temporary or permanent nature which modifies structures, land, wetlands, or shorelines and which does not fall within the allowable exemptions contained in the City Code.

**Enhancement** – The manipulation of the physical, chemical, or biological characteristics of a wetland to heighten, intensify, or improve specific function(s) or to change the growth stage or composition of the vegetation present. Enhancement is undertaken for specified purposes such as water quality improvement, flood water retention, or wildlife habitat. Enhancement results in a change in wetland function(s) and can lead to a decline in other wetland functions, but does not result in a gain in wetland acres. Examples are planting vegetation, controlling non-native or invasive species, and modifying site elevations to alter hydroperiods.

**Estuarine Wetland** – A vegetated wetland with a water regime that is predominately tidal, as described in *Washington State Wetland Rating System for Western Washington: 2014 Update* (Washington State Department of Ecology Publication #14-06-29, Olympia, WA, October 2014).

**Functions and Values** – The services provided by critical areas to society, including, but not limited to, improving and maintaining water quality, providing fish and wildlife habitat, supporting terrestrial and aquatic food chains, reducing flooding and erosive

flows, wave attenuation, historical or archaeological importance, educational opportunities, and recreation.

**Growth Management Act** – RCW 36.70A and 36.70B, as amended.

**Hazardous Substances** – Any liquid, solid, gas, or sludge, including any material, substance, product, commodity, or waste, regardless of quantity, that exhibits any of the physical, chemical, or biological properties described in WAC 173-303-090 or 173-303-100.

**Impervious Surface** – A surface area which either prevents or retards the entry of water into the soil mantle as under natural conditions prior to development. A non-vegetated surface area which causes water to run off the surface in greater quantities or at an increased rate of flow from the flow present under pre-development or pre-developed conditions. Common impervious surfaces include, but are not limited to, roof tops, walkways, patios, driveways, parking lots or storage areas, concrete or asphalt paving, gravel roads, packed earthen materials, and oiled, macadam or other surfaces which similarly impede the natural infiltration of stormwater.

**In-Kind Compensation** – To replace critical areas with substitute areas whose characteristics and functions closely approximate those destroyed or degraded by a regulated activity.

**In-Lieu-Fee Program** – An agreement between a regulatory agency (state, federal, or local) and a single sponsor, generally a public natural resource agency or non-profit organization. Under an in-lieu-fee agreement, the mitigation sponsor collects funds from an individual or a number of individuals who are required to conduct compensatory mitigation required under a wetland regulatory program. The sponsor may use the funds pooled from multiple permittees to create one or a number of sites under the authority of the agreement to satisfy the permittees' required mitigation.

**Infiltration** – The downward entry of water into the immediate surface of soil.

**Interdunal Wetland** – A wetland that forms in the deflation plains and swales that are geomorphic features in areas of coastal dunes, as described in *Washington State Wetland Rating System for Western Washington: 2014 Update* (Washington State Department of Ecology).

**Isolated Wetland** – A wetland that is hydrologically isolated from other aquatic resources, as determined by the United States Army Corps of Engineers (USACE). Isolated wetlands may perform important functions and are protected by state law (RCW 90.48) whether or not they are protected by federal law.

**Mature and Old-Growth Forested Wetland** – A wetland having at least 1 contiguous acre of either old-growth forest or mature forest, as described in *Washington State Wetland Rating System for Western Washington: 2014 Update* (Washington State Department of Ecology Publication #14-06-29, Olympia, WA, October 2014).

**Mitigation** – Avoiding, minimizing, or compensating for adverse critical areas impacts. Mitigation, in the following sequential order of preference, is:

- (a) Avoiding the impact altogether by not taking a certain action or parts of an action;
- (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation by using appropriate technology or by taking affirmative steps to avoid or reduce impacts;
- (c) Rectifying the impact to wetlands, critical aquifer recharge areas, and habitat conservation areas by repairing, rehabilitating, or restoring the affected environment to the conditions existing at the time of the initiation of the project;
- (d) Reducing or eliminating the impact or hazard over time by preservation and maintenance operations during the life of the action;
- (e) Compensating for the impact to wetlands, critical aquifer recharge areas, and habitat conservation areas by replacing, enhancing, or providing substitute resources or environments; and
- (f) Monitoring the hazard or other required mitigation and taking remedial action when necessary.

Mitigation for individual actions may include a combination of the above measures.

**Monitoring** – Evaluating the impacts of development proposals on the biological, hydrological, and geological elements of such systems, and assessing the performance of required mitigation measures through the collection and analysis of data by various methods for the purpose of understanding and documenting changes in natural ecosystems and features. Monitoring includes gathering baseline data.

**Native Vegetation** – Plant species that occur naturally in a particular region or environment and were present before European colonization.

**Off-Site Compensation** – To replace critical areas away from the site on which a critical area has been impacted.

**On-Site Compensation** – To replace critical areas at or adjacent to the site on which a critical areas has been impacted.

**Ordinary High Water Mark** – That mark which is found by examining the bed and banks of water bodies and ascertaining where the presence and action of waters are so common and usual, and so long continued in all ordinary years, that the soil has a character distinct from that of the abutting upland in respect to vegetation.

**Preservation** – The removal of a threat to, or preventing the decline of, wetland conditions by an action in or near a wetland. This term includes the purchase of land or conservation easements, repairing water control structures or fences, or structural protection. Preservation does not result in a gain of wetland acres but may result in a gain in functions over the long term.

**Project Area** – All areas, including those within fifty (50) feet of the area, proposed to be disturbed, altered, or used by the proposed activity or the construction of any proposed structures. When the action binds the land, such as a subdivision, short subdivision, binding site plan, planned unit development, or rezone, the project area shall include the entire parcel, at a minimum.

**Prior Converted Croplands** – Prior converted croplands (PCCs) are defined in federal law as wetlands that were drained, dredged, filled, leveled, or otherwise manipulated, including the removal of woody vegetation, before December 23, 1985, to enable production of an agricultural commodity, and that: 1) have had an agricultural commodity planted or produced at least once prior to December 23, 1985; 2) do not have standing water for more than 14 consecutive days during the growing season, and 3) have not since been abandoned.

**Qualified Professional** – A qualified professional for wetlands must be a professional wetland scientist with at least two years of full-time work experience as a wetlands professional, including delineating wetlands using the federal manual and supplements, preparing wetlands reports, conducting function assessments, and developing and implementing mitigation plans.

**Re-establishment** – The manipulation of the physical, chemical, or biological characteristics of a site with the goal of returning natural or historic functions to a former wetland. Re-establishment results in rebuilding a former wetland and results in a gain in wetland acres and functions. Activities could include removing fill, plugging ditches, or breaking drain tiles.

**Rehabilitation** – The manipulation of the physical, chemical, or biological characteristics of a site with the goal of repairing natural or historic functions and processes of a degraded wetland. Rehabilitation results in a gain in wetland function but does not result in a gain in wetland acres. Activities could involve breaching a dike to reconnect wetlands to a floodplain or returning tidal influence to a wetland.

**Repair or Maintenance** – An activity that restores the character, scope, size, and design of a serviceable area, structure, or land use to its previously authorized and undamaged condition. Activities that change the character, size, or scope of a project beyond the original design and drain, dredge, fill, flood, or otherwise alter critical areas are not included in this definition.

**Restoration** – Measures taken to restore an altered or damaged natural feature, including:

- (a) Active steps taken to restore damaged wetlands, streams, protected habitat, or their buffers to the functioning condition that existed prior to an unauthorized alteration; and
- (b) Actions performed to re-establish structural and functional characteristics of a critical area that have been lost by alteration, past management activities, or catastrophic events.

**SEPA** – Washington State Environmental Policy Act, 43.21C RCW.

**Service Area** – The geographic area within which impacts can be mitigated at a specific mitigation bank or an in-lieu-fee program, as designated in its instrument.

**Soil Survey** – The most recent soil survey for the local area or county by the National Resources Conservation Service, U.S. Department of Agriculture.

**Species** – Any group of animals or plants classified as a species or subspecies as commonly accepted by the scientific community.

**Species of Local Importance** – Those species of local concern designated by the City in Chapter XX.XX due to their population status or their sensitivity to habitat manipulation.

**Species, Listed** -- Any species listed under the federal Endangered Species Act or state endangered, threatened, and sensitive, or priority lists (see WAC 232-12-297 or page 6 of “Priority Habitat and Species List,” Washington Department of Fish and Wildlife, 2008, Olympia, Washington. 177 pp.)

**Stream** – An area where open surface water produces a defined channel or bed, not including irrigation ditches, canals, storm or surface water runoff devices, or other entirely artificial watercourses, unless they are used by salmonids or are used to convey a watercourse naturally occurring prior to construction. A channel or bed need not contain water year-round, provided there is evidence of at least intermittent flow during years of normal rainfall.

**Unavoidable Impacts** – Adverse impacts that remain after all appropriate and practicable avoidance and minimization has been achieved.

**Washington Administration Code (WAC)** – Administrative rules implementing state laws.

**Wetlands** – Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas. Wetlands do not include those artificial wetlands intentionally created from non-wetland sites, including, but not limited to, irrigation and drainage ditches, grass-lined swales, canals, detention facilities, wastewater treatment facilities, farm ponds, and landscape amenities, or those wetlands created after July 1, 1990, that were unintentionally created as a result of the construction

of a road, street, or highway. Wetlands may include those artificial wetlands intentionally created from non-wetland areas to mitigate the conversion of wetlands.

**Wetland of High Conservation Value** – A wetland that has been identified by scientists from the Washington Natural Heritage Program (WHNHP) as an important ecosystem for maintaining plant diversity in Washington State. See <http://www.dnr.wa.gov/data-information-natural-heritage-features> .

**Wetland Mitigation Bank** – A site where wetlands are restored, created, enhanced, or in exceptional circumstances, preserved, expressly for the purpose of providing compensatory mitigation in advance of unavoidable impacts to wetlands or other aquatic resources that typically are unknown at the time of certification to compensate for future, permitted impacts to similar resources.

**Wetland Mosaic** – An area with a concentration of multiple small wetlands, in which each patch of wetland is less than one acre; on average, patches are less than 100 feet from each other; and areas delineated as vegetated wetland are more than 50% of the total area of the entire mosaic, including uplands and open water.

# RIPARIAN ECOSYSTEMS, VOLUME 2: MANAGEMENT RECOMMENDATIONS

*A PRIORITY HABITATS AND SPECIES DOCUMENT OF THE  
WASHINGTON DEPARTMENT OF FISH AND WILDLIFE*

December 2020

*This document should be cited as follows:*

Riparian Ecosystems, Volume 2: Management Recommendations. 2020. Amy Windrope, Terra Rentz, Keith Folkerts, and Jeff Azerrad. A Priority Habitats and Species Document of the Washington Department of Fish and Wildlife, Olympia, Washington.

## ACKNOWLEDGMENTS

**Land Acknowledgement:** We acknowledge the traditional, ancestral, territory of Washington state on which we are learning, working, and organizing today. We recognize the longstanding history that has brought us to reside on this land and seek to understand those who first lived here.

Many people were involved with creation of both Volumes 1 and 2 for Priority Habitats and Species (PHS) Riparian Ecosystems. WDFW extends our sincere appreciation to the following individuals and organizations that played important roles during development and/or review of both volumes.

The Washington Department of Ecology (Ecology) and U.S. Environmental Protection Agency (EPA) provided funds that made this document possible (Contract C1300107).

The Washington State Academy of Sciences, with coordination by Dr. Robert Bates, provided an independent peer review that improved the scientific rigor of Volume 1.

Federal (EPA and NOAA Fisheries) and tribal entities (individual tribes, the Northwest Indian Fisheries Commission, Columbia River Inter-Tribal Fish Commission, and Upper Columbia United Tribes) as well as numerous state agencies (Washington State departments of Ecology, Natural Resources, and Commerce; Recreation and Conservation Office; Washington State Conservation Commission; and Puget Sound Partnership) reviewed draft versions of this document. During the summer 2018 public comment period, local governments and members of the public provided valuable feedback that led to a more concise and user-friendly final version of Volume 2.

Within WDFW, Keith Folkerts led coordination, contract planning and budgeting for this work. Tim Quinn and George Wilhere were integral in ensuring a strong relationship with information in Volume 1 and provided additional valuable feedback on multiple drafts. Terry Johnson developed the Site-Potential Tree Height mapping tool and wrote the associated user guide information in the Appendix to this Volume 2. Alison Hart produced final graphics and ensured consistent formatting and stylistic usage throughout. Mary Huff provided editorial support, improved the document's organization, and (in late 2020) took it across the finish line.

WDFW recognizes and appreciates the significant role that tribes, local governments, conservation organizations, and others play in accomplishing our agency's mission. Indeed, we are certain that without these concerted efforts to designate and protect the riparian ecosystems that are essential for most of the state's fish and wildlife species, WDFW would be unable to fulfill its mandate on behalf of all of Washington's residents.

While we acknowledge and have deep appreciation for all the review and comments provided, WDFW bears sole responsibility for this document and any errors contained herein.

# CHAPTER 1. OVERVIEW

## 1.1 OUR ROLE AS WASHINGTON’S CONSERVATION AGENCY

The mission of the Washington Department of Fish and Wildlife (WDFW) is to preserve, protect, and perpetuate the state’s fish, wildlife, and ecosystems while providing sustainable fish and wildlife recreational and commercial opportunities.

We offer the following science-based guidance to further that mission through the preservation, protection, and—where possible—restoration of healthy, intact, and fully functioning riparian ecosystems statewide. As described throughout this volume, we believe that protection *and* restoration<sup>1</sup> of Washington’s riparian ecosystems is a foundational conservation action; considering a growing population and changing climate, it is also an urgent one.

Within the State of Washington’s land use decision-making framework, WDFW’s role is that of advisor. We provide information relative to our mission about the habitat needs of fish and wildlife, and the likely implications of various land use decisions on those resources over time. Through the Priority Habitats and Species (PHS) Program, we work cooperatively with land use decision makers and landowners to facilitate solutions that accommodate their needs *and* the needs of fish and wildlife. We provide this PHS document, *Riparian Ecosystems Volume 2: Management Recommendations* in support of that effort.

Priority Habitats are places that warrant special consideration for protection when land use decisions are made and should also be prioritized for restoration or enhancement wherever possible. To qualify as a “Priority Habitat” in WDFW’s PHS program, an ecosystem or habitat component must provide unique or significant value to many species. Specifically, it must have one or more of the following attributes (WDFW 2008):

- Comparatively high fish and wildlife density
- Comparatively high fish and wildlife species diversity
- Important fish or wildlife breeding habitat

---

### WDFW’S MISSION

To preserve, protect, and perpetuate Washington’s fish, wildlife, and ecosystems while providing sustainable fish and wildlife recreational and commercial opportunities.

### WDFW’S RIPARIAN VALUES

We value the protection and restoration of healthy, intact, and fully functioning riparian ecosystems statewide.

### WDFW’S RECOMMENDATION

---

Within the context of wise watershed management, preserve, protect, and—where possible—restore the full extent of riparian ecosystems.

---

<sup>1</sup> Restoration of riparian ecosystems is critically important because legacy of environmental impacts resulting from the ways land use has affected riparian areas over the past 200 years. In other words, what remains available for protection is not enough to provide the full functions and values Washington’s fish and wildlife need.

- Important fish or wildlife seasonal ranges
- Important fish or wildlife movement corridors
- Limited availability
- High vulnerability to habitat alteration
- Unique or dependent species

Riparian areas (comprised of riparian ecosystems, active floodplains, and riverine wetlands) meet all these criteria, and were among the first Priority Habitats described by WDFW. Riparian areas provide important ecological functions that help create and maintain aquatic habitats in addition to supporting terrestrial wildlife. Riparian areas alongside rivers and streams are the focus of this document, however much of the science reviewed in Volume 1 and the recommendations in this Volume 2 are relevant for lakes, ponds, and marine shorelines as well.

As previously mentioned, one role of WDFW in land use decision making is that of advisor. In that role, recommendations like those contained in this document and in complementary PHS documents (available at <https://wdfw.wa.gov/species-habitats/at-risk/phs/recommendations>) provide critical information for the protection (and where necessary, recovery) of Washington's fish and wildlife. We recognize landowners and land managers most often face situations where various human needs must also be met; and thus, considerations other than fish and wildlife will be incorporated into land use decision making.

The information presented in this management recommendation document is not, in and of itself, science. Rather, it consists of policy recommendations which are informed by the best available science summarized in Volume 1<sup>2</sup> and which reflect WDFW's mission and legislative mandate. To that end, these recommendations represent WDFW's guidance for the protection and restoration of healthy, intact, and fully functioning riparian ecosystems and

---

## Ecosystem Based Management & WDFW's Conservation Principles

In 2013, WDFW adopted ecosystem-based management principles into policy (WDFW Policy 5004). Ecosystem-based management is an integrated, science-based approach to natural resource management that aims to sustain the ability of ecosystems to provide goods and services upon which humans and other species depend. Importantly, ecosystem-based management recognizes the magnitude of humans as change agents in the ecosystem, and the role of social, economic, and ecological factors in managing complex and dynamic systems.

We believe that conservation is best achieved through employing the following ecosystem-based management principles:

1. We practice conservation by managing, protecting, and restoring ecosystems for the long-term benefit of people, and for fish wildlife and their habitats.
  2. We work across disciplines to solve problems because of their connections among organisms, species and habitats.
  3. We integrate ecological, social, economic, and institutional perspectives into our decision-making.
  4. We embrace new knowledge and apply best science to address changing conditions through adaptive management.
  5. We collaborate with our co-managers and conservation and community partners to help us achieve our shared goals.
- 

---

<sup>2</sup> The original manuscript of *Riparian Ecosystems, Volume 1: Science Synthesis and Management Implications* was publicly released in May 2018. In 2020, the format of the document was professionally designed, which included making limited updates to content focused on copyediting and improving usability. In accordance with standard citation practice, Volume 1 is now cited as having a 2020 publication date, but substantively, the current document is equivalent to the original 2018 version.

for how land managers and land use regulators can utilize best available science to protect these ecosystems within the scope of their authority and/or ability.

For example, local governments are encouraged to use information provided through PHS to guide critical area ordinance (CAO) updates and other land use policies, plans, or regulations. More specifically, WDFW advises using the information in this PHS Riparian Volume 2 for designating riparian areas as Fish and Wildlife Habitat Conservation Areas (FWHCAs) and protecting them for their inherent value, rather than just as buffers for rivers and streams. This is because riparian areas are so important for helping sustain endangered, threatened, and sensitive species; providing habitat connectivity for both aquatic and terrestrial wildlife; and for their critical role in protecting salmonid habitat (WAC 365-190-130).

In short, Volumes 1 and 2 focus on the science and management, respectively, of riparian ecosystems to support fish and aquatic wildlife species. Volume 1 characterizes riparian ecosystem functions and essential processes, while Volume 2 provides management guidance for riparian ecosystems in the context of watershed processes. To be clear, these two volumes do *not* provide a summary of science or recommendations regarding the contribution of riparian ecosystems for the protection of terrestrial wildlife species. However, our first generation PHS Riparian-specific document, *Management Recommendations for Washington's Priority Habitats: Riparian* (Knutson and Naef 1997) does provide terrestrial species information related to riparian areas. Further, PHS has separate, species-specific management recommendations that address the needs of many terrestrial Priority Species.

This document provides recommendations applicable across the State of Washington but does not address unusual, site-scale environmental conditions or issues specific to particular ecological communities. We strongly encourage addressing such matters at a local level with the assistance of WDFW regional habitat biologists, and other technical experts and stakeholders such as tribal biologists and conservation organizations.

## 1.2 PURPOSE AND APPLICABILITY OF VOLUME 2

The purpose of this document is to provide guidance to protect and—where possible—restore healthy, intact, and fully functioning riparian ecosystems, which are fundamental for clean water, healthy salmon populations, and climate resilient watersheds.

Volume 2 provides information to:

- Protect existing and restore degraded riparian ecosystem functions in support of aquatic and terrestrial species recovery;
- Assist local governments with their responsibilities to protect priority fish and wildlife and their habitats;
- Assist landowners and local groups in implementing voluntary restoration actions on and off working lands; and
- Incorporate monitoring and adaptive management to understand how well regulatory and non-regulatory efforts are protecting riparian functions and values.

This guidance is applicable to riparian ecosystems statewide. We offer a specific focus on lands within the purview of the Growth Management Act (GMA) and Shoreline Management Act (SMA), although a broader application by local governments and other users is also appropriate.

While many other federal, state, and tribal government programs and policies pertain to riparian ecosystems, they are not specifically addressed in this document. For instance, we do not discuss holistic protection of floodplains, nor do we discuss specific Endangered Species Act (ESA) requirements relative to listed salmonids and other species. Also, we do not address commercial forestlands that fall under the jurisdiction of the Forest Practices Act (FPA), or the Department of Ecology's clean water regulations. These other programs and policies were developed with specific goals and objectives that may be different from the goals of this document, and as such may differ with guidance provided herein.

### 1.3 SCIENCE SYNTHESIS AND MANAGEMENT IMPLICATIONS (VOLUME 1) SUMMARY

As stated above, Volume 1 (Quinn et al. 2020; see footnote 2) provides important information integral to the development of these management recommendations. It includes both overarching as well as specific considerations important to all efforts, large and small, to protect rivers and streams for the benefit of the aquatic species associated with them. Volume 1 focuses on the science of riparian ecosystems—specifically, how riparian areas interact with large-scale drivers (e.g., topography, geology, climate, and land use) and watershed processes to create and maintain riparian and aquatic habitat in support of fish and wildlife. Thus, we provide here an explicit definition of riparian ecosystems from Volume 1 that combines a variety of conceptual riparian descriptions from the scientific literature:

Riparian ecosystems are transitional between terrestrial and aquatic ecosystems, distinguished by gradients in biophysical conditions, ecological processes, and biota. They are areas through which surface and subsurface hydrology connect waterbodies with adjacent uplands. They include those portions of terrestrial ecosystems (i.e., *a zone of influence*) that significantly influence exchanges of energy and matter with aquatic ecosystems and the portion of the ecosystem characterized by moist soils and plants adapted to periodically saturated soils – the *riparian zone* (RZ). The width of the riparian ecosystem is typically defined by the outer edge of the zone of influence, which, in forested regions, is based on site-potential tree height (SPTH) measured from the edge of the active channel. While our definition of riparian ecosystem does not include the water in river or streams, it does include riverine wetlands and recognizes the riparian zone as a distinctive area within riparian ecosystems.

To assist managers in understanding important implications of the science synthesized in Volume 1, we reiterate the ten overarching findings of that document below. These findings are also discussed in more detail in later chapters.

1. Protection and restoration of riparian ecosystems continues to be critically important because: (a) they are disproportionately important, relative to area, for aquatic species (e.g., salmon) and terrestrial wildlife; (b) they provide ecosystem services such as water purification and fisheries (Naiman and Bilby 2001, NRC 2002, Richardson et al. 2005); and (c) by interacting with watershed-scale processes, they contribute to the creation and maintenance of aquatic habitats.
2. Stream riparian ecosystems encompass the riparian zone; the active floodplain, including riverine wetlands and the terraces; and adjacent uplands that contribute matter and energy

to the active channel or active floodplain (Gregory et al. 1991, Naiman and Bilby 1998). Such terraces and adjacent uplands are called the zone of influence.

3. The width of the riparian ecosystem is estimated by one 200-year SPTH measured from the edge of the active channel or active floodplain. Protecting functions within at least one 200-year SPTH is a scientifically supported approach if the goal is to protect and maintain full function of the riparian ecosystem.
4. Where the riparian zone is narrow (<100 ft [30 m]) and the zone of influence lacks tall trees (<100 ft), (e.g., in parts of the Columbia Plateau Ecoregion), the pollution removal function may determine the width of the zone of influence.
5. The riparian ecosystem begins at the edge of the active channel or active floodplain, whichever is wider. As the active channel moves back and forth across the channel migration zone (CMZ), the riparian ecosystem moves with it. Consequently, there are times when the riparian ecosystem lies adjacent to or overlaps the CMZ (see Figure 2.3). Hence, to maintain riparian ecosystem functions, management must anticipate and protect future locations of the riparian ecosystem.
6. A near consensus of scientific opinion holds that the most effective and reliable means of maintaining viable self-sustaining fish, especially salmon, and wildlife populations is to maintain/restore ecosystems to conditions that resemble or emulate their historical range of natural variability (Swanson et al. 1994, Reeves et al. 1995, Bisson et al. 2009). This opinion is based in part on the complexity of processes that affect the expression of habitats over time and space.
7. The protection and restoration of watershed-scale processes, especially related to hydrology, water quality, connectivity, and inputs of wood, shade, and sediment are important for aquatic system function, and help maximize the ecological benefits of riparian ecosystem protections.
8. Riparian areas and surrounding watersheds are complex and dynamic systems comprised of many interacting components. Natural disturbances (flood, fire, and landslides) across the watershed and through time create the mosaic of conditions necessary for self-sustaining populations of fish, especially salmon, and other aquatic organisms.
9. Impending changes to aquatic systems as a result of climate change increase risk to species already threatened by human activities. The effects of climate change on rivers and streams threaten to reduce fish distribution and viability throughout the Pacific Northwest (Beechie et al. 2013).
10. The use of the precautionary principle and adaptive management are particularly appropriate when dealing with complex and dynamic systems, and when we have uncertainty related to exactly how management activities affect functioning of watersheds and riparian ecosystems.

## 1.4 KEY FINDINGS AND RECOMMENDATIONS

WDFW recognizes that there is a significant amount of work currently being done throughout the state to protect and restore riparian areas. This focus is longstanding and has ranged from regulatory protections that guide Washington's growing population to voluntary conservation on our working lands. Below, we highlight what we believe—based on best available science and our agency's mission—are the most important recommendations to ensure healthy, intact, and fully functioning riparian ecosystems that provide for the preservation, protection and perpetuation of Washington's fish and wildlife:

1. **Designate riparian ecosystems as critical areas:** WDFW recognizes riparian ecosystems as a Priority Habitat for fish and wildlife and recommends that local jurisdictions designate those ecosystems as Fish and Wildlife Habitat Conservation Areas (FWHCAs), a type of critical area. We define the bounds of the riparian ecosystem as the riparian management zone (RMZ), and this RMZ should be designated as the location where protection and restoration of riparian ecosystem functions and values are addressed. RMZs provide a framework for delineating, evaluating, planning, and managing functions and values. In this volume, we provide a process for RMZ delineation (Chapter 2).
2. **Include watershed-scale management considerations:** Watershed-scale management is critical to realizing the full benefits of riparian ecosystem protection and restoration. Certain types of anthropogenic changes at the watershed scale can dramatically reduce the effectiveness of riparian ecosystems to protect aquatic habitat. For example, unmitigated delivery of stormwater from impervious surfaces like roads, parking lots, and rooftops to streams, for example, dramatically increases peak stream flows, alters channel form, and short-circuits the capacity of riparian areas to remove pollutants from runoff. Similarly, road-crossing culverts that are impassible to fish can reduce stream-network connectivity and dramatically reduce amounts of otherwise suitable habitat.
3. **Use reference points to locate the inner edge of the RMZ:**
  - For streams without Channel Migration Zones (CMZs), the inner edge of the RMZ should be delineated starting at the outer edge of active floodplain, if this has or can be determined; otherwise, from the active channel, as delineated by the Ordinary High-Water Mark (OHWM)<sup>3</sup>.
  - For streams with CMZs, the unpredictable nature of channel migration should be accommodated through delineation of an RMZ that encompasses both the entire CMZ and future locations of the riparian ecosystem. In these instances, the inner edge of the RMZ should be located at the outer edge of the CMZ.

Whether or not a stream has a CMZ, the distance from the inner edge of the RMZ to the outer edge of the RMZ should be one SPTH<sub>200</sub>.

---

<sup>3</sup> Active floodplain delineations are rarely available, and we currently lack a repeatable, well-vetted, and widely accepted method for the delineation of active floodplains. Therefore, until such a process is developed, we recommend delineating the RMZ's inner edge using the OHWM for streams without CMZs.

4. **Include CMZs in delineation of the RMZ:** CMZs are important to protect for maintaining riparian functions and values, and so are included in the delineation of RMZs. Over time, a riparian ecosystem will occupy different parts of the CMZ and uplands outside the CMZ. Lateral channel migration and related streambank erosion processes can pose risks to homes and communities located near rivers; however, when channels are constrained from moving, aquatic and riparian ecosystems may degrade over time. To maintain riparian ecosystem functions, land managers must anticipate and protect future locations of the riparian ecosystem and thus delineate the RMZ accordingly.
5. **Establish RMZ widths based on site-specific conditions:** From the perspective of those riparian ecosystem functions affecting aquatic systems, the width of the riparian ecosystem varies with ecological conditions. The most efficient way to protect riparian functions is to adopt protections that recognize these differences, rather than uniform-width (i.e., one-size-fits-all) RMZs, as these may result in over-protection in some places and under-protection in others.
  - a. **In forested ecoregions, start with SPTH<sub>200</sub>:** At most riparian areas in forested ecoregions, SPTH<sub>200</sub> is 100 feet or greater, and so the RMZ is delineated using one SPTH<sub>200</sub>. If SPTH<sub>200</sub> is less than 100 feet, the RMZ is delineated by the pollution removal function (see below). In highly altered areas where soil data are not available, it may be necessary to estimate SPTH<sub>200</sub> values based on nearby soils.
  - b. **In dryland ecoregions, start with SPTH<sub>200</sub> (if available), or the width of the riparian vegetation community:** If site conditions do not support tree species or SPTH<sub>200</sub> is less than 100 feet, then RMZ width is determined by the full extent of all riparian vegetation (the riparian zone) or by the pollution removal function—see below.
  - c. **For both forested and dryland ecoregions, use the pollution removal function when appropriate:** Where the SPTH<sub>200</sub> and/or the width of the riparian vegetative community is less than 100 feet, we recommend that RMZ width be delineated at a minimum of 100 feet, as this provides the width necessary for 95% pollution removal target for most pollutants (approximately 85% for surface nitrogen.)<sup>4</sup>

To aid with site-specific RMZ delineation, WDFW created an internet-based mapping tool that reports recommended widths for RMZs (Appendix 1) statewide based on SPTH<sub>200</sub>. The tool also notes instances where a 100-foot RMZ should be applied to support the pollution removal function.

6. **Apply the recommended RMZ delineation steps to all streams, whether or not they are fish-bearing:** In 1997, WDFW recommended a lower level of protection for non-fish bearing streams than fish-bearing streams. In reviewing the current science literature for Volume 1, we found no evidence that full riparian ecosystem functions along non-fish-bearing streams are less important to aquatic ecosystems than full riparian ecosystem

---

<sup>4</sup> See Chapter 2, Section 2.3.5 for more information about surface nitrogen removal and other site-specific characteristics that may require RMZ distances greater than 100 feet in order to ensure an adequate pollution removal function.

functions along fish-bearing streams. This recommendation is based on four additional considerations. Non-fish-bearing streams:

- Support a unique community of aquatic and riparian-obligate wildlife;
- Provide movement corridors for wildlife, particularly in the face of changing climate conditions;
- Provision fish-bearing streams with matter and energy; and
- Provide cool water to downstream reaches. Washington State has already experienced increased stream temperatures due to climate change and expect further increases, which have direct implications for the persistence of fish.

7. **Establish monitoring and adaptive management frameworks:** We believe it is critical to understand if riparian ecosystems protections are working as intended, and if not, to adjust them accordingly. We recommend the establishment of monitoring and adaptive management designed to improve (where necessary) local permit implementation and compliance, and to increase effectiveness of actions intended to protect aquatic species.

8. **Consider needs of relevant terrestrial species:** As stated earlier, a review of new literature related to the needs of terrestrial Priority Species was not a focus of Volume 1.

Nonetheless, riparian areas provide important functions for threatened, endangered, and sensitive terrestrial wildlife that require consideration by landowners and land managers. WDFW regional habitat biologists, tribal biologists and/or other local habitat experts can assist in identification of site-specific terrestrial species needs. Because riparian protections

---

## WAC 365-190-130

### FISH AND WILDLIFE HABITAT CONSERVATION AREAS

(1) "Fish and wildlife habitat conservation" means land managed for maintaining populations of species in suitable habitats within their natural geographic distribution, so that the habitat is sufficient to support viable populations over the long term and isolated subpopulations are not created. This does not mean maintaining all individuals of all species at all times, but it does mean not degrading or reducing populations or habitats so that they are no longer viable over the long term. Counties and cities should engage in cooperative planning and coordination to help assure population viability.

Fish and wildlife habitat conservation areas contribute to the state's biodiversity and occur on both publicly- and privately-owned lands. Designating these areas is an important part of land use planning for appropriate development densities, urban growth area boundaries, open space corridors, and incentive-based land conservation and stewardship programs."

## WAC 173-26-186

### GOVERNING PRINCIPLES OF THE [SMP] GUIDELINES

(8) "Through numerous references to and emphasis on the maintenance, protection, restoration, and preservation of "fragile" shoreline "natural resources," "public health," "the land and its vegetation and wildlife," "the waters and their aquatic life," "ecology," and "environment," the act makes protection of the shoreline environment an essential statewide policy goal consistent with other policy goals of the act. It is recognized that shoreline ecological functions may be imparted not only by shoreline development subject to the substantial development permit requirements of the act but also by past actions, unregulated activities, and development that is exempt from the act's permit requirements. The principle regarding protecting shoreline ecological systems is accomplished by these guidelines in several ways, and in the context of related principles."

benefit both aquatic and many terrestrial wildlife species, concentrating protections around riparian areas may also be an efficient use of resources.

## 1.5 RELATIONSHIP WITH WASHINGTON’S DEVELOPMENT LAWS AND REGULATIONS

### 1.5.1 *Relationship with the Growth Management Act (GMA)*

The GMA requires local jurisdictions to designate and protect critical areas, and in so doing, use best available science and give special consideration to anadromous species<sup>5</sup>. The GMA also encourages state agencies to provide technical assistance to counties and cities in the review of their critical areas ordinances (CAOs), comprehensive plans, and development regulations [RCW [36.70A.130\(6\)\(g\)](#)]. While the Washington State Department of Commerce (Commerce) administers the GMA, WDFW is the lead state agency for advising local governments on matters related to one type of critical area: Fish and Wildlife Habitat Conservation Areas (FWHCAs), and we produce PHS Management Recommendations like this Volume 2 in support of that role.

This document provides guidance that is consistent with the GMA, under which local governments exercise their land use responsibilities: specifically, protection of the functions and values of critical areas. It also reflects the legal and policy framework within which WDFW and the PHS program operate, which includes among other things providing a source of best available science necessary to support local governments in distinguishing and delineating those critical areas (e.g., FWHCAs).

WDFW understands that local jurisdictions have existing critical area regulations that have been approved by elected officials and in many cases have been found to be compliant with GMA through the Growth Management Hearings Board and courts. We acknowledge that revising a critical area regulation can be a lengthy, expensive, and contentious process, and so jurisdictions frequently do not make updates to their CAOs more frequently than required by law or rule. In this volume, we aim to be more precise about where recent science has improved our certainty around the need for riparian protections, as well as for specific practices; and how to incorporate best available science and WDFW’s management recommendations.

WDFW also recommends local jurisdictions continue considering PHS best available science (e.g., Volume 1; PHS maps), incorporating PHS Management Recommendations, and seeking technical assistance from WDFW’s regional habitat biologists not just when updating and implementing critical area policies and regulations, but in all land use planning efforts.

### 1.5.2 *Relationship with the Shoreline Management Act (SMA)*

As with GMA, WDFW plays a role of technical advisor under SMA, working directly through locally led development processes, with the goal of addressing needs for fish and wildlife. Under SMA, the Department of Ecology (Ecology) has a role approving Shoreline Master Program (SMP) updates when they are deemed consistent with all statutory and regulatory requirements. Ecology also has

---

<sup>5</sup> RCW 36.70A.172(1): “In designating and protecting critical areas under this chapter, counties and cities shall include the best available science in developing policies and development regulations to protect the functions and values of critical areas. In addition, counties and cities shall give special consideration to conservation or protection measures necessary to preserve or enhance anadromous fisheries.”

a direct role in implementation of SMPs, including issuing the final decision to approve, deny, or put conditions on locally issued conditional use permits and variances. [Under GMA, Commerce does not approve comprehensive plan updates or CAOs.]

The goal of SMA is “to prevent the inherent harm in an uncoordinated and piecemeal development of the state’s shorelines” (RCW [90.58.020](#)). To achieve that end, WDFW recommends local jurisdictions designate riparian areas and provide the same levels of protection for them within the SMA jurisdiction areas as they do under GMA. While the SMA does not apply to streams with 20 cubic feet per second (cfs) or less mean annual flow, we recommend the application of the guidelines in this Volume 2 to all rivers and streams, regardless of size.

## 1.6 ORGANIZATION OF VOLUME 2

Chapter 1 aims to establish Volume 2’s purpose and intent; articulate WDFW’s values; and provide policy context regarding protection and designation of riparian ecosystems.

In Chapter 2, we define the RMZ based on SPTH<sub>200</sub> with special considerations for urban and dryland landscapes; and provide a stepwise process for identifying and delineating the RMZ both for requiring riparian protections and for classifying RMZs as a FWHCA under GMA.

Chapter 3 articulates policies, plans, and practices that protect riparian ecosystems. WDFW recognizes that counties and cities have a long history of providing such protections, and the responsibility to include best available science when updating CAOs. The protection recommendations described in this chapter are intended to help counties and cities moving forward with reviewing and updating their CAOs and other relevant policies and plans.

Chapter 4 explains the importance of restoration in riparian management, which is necessary for recovery of the degraded riparian functions present in many locations and is critical to recover salmon stocks and preserve Washington’s riparian-dependent Priority Species. To that end, we outline voluntary approaches to improve riparian functions. Although Volume 2 is not a restoration guide, it is applicable to restoration practitioners in that it describes management actions that enhance riparian functions and values. We do not address restoration project design or standards but provide links within this chapter to resources that do.

Chapter 5 will assist with developing monitoring programs in support of adaptive management, designed to ensure transparent programs that consistently deliver sufficient protection of riparian functions. Careful monitoring and adaptive management are particularly important when a land use may harm a critical area and scientific information about the likely severity of harm is lacking. Although specific to local governments, this chapter provides valuable resources for any land manager interested in engaging in adaptive management.

Finally, this volume includes an appendix that contains a “how-to” process for utilizing WDFW’s SPTH mapping tool to help determine recommended minimum RMZ widths around the state. The tool itself is available at [wdfw.maps.arcgis.com/apps/MapSeries/index.html?appid=919ea98204eb4f5fa70eca99cd5b0de1](http://wdfw.maps.arcgis.com/apps/MapSeries/index.html?appid=919ea98204eb4f5fa70eca99cd5b0de1).

# CHAPTER 2. RIPARIAN MANAGEMENT ZONE DELINEATION

## 2.1 INTRODUCTION

We define the extent of the riparian ecosystem as the area that provides full ecological function for bank stability, shade, pollution removal, contributions of detrital nutrients, and recruitment of large woody debris. For the purposes of management or regulatory protection, the riparian management zone (RMZ) encompasses the riparian ecosystem, and—when present—the channel migration zone (CMZ) to account for lateral movement of the riparian ecosystem over time. RMZs can also provide habitat for many terrestrial wildlife species including movement corridors. WDFW categorizes the riparian ecosystem as a Priority Habitat, and thus recommends local jurisdictions designate all riparian areas as critical areas: specifically, Fish and Wildlife Habitat Conservation Areas (FWHCAs), as mentioned in Chapter 1.

The RMZ provide an initial framework for delineating, assessing, planning, and managing riparian ecosystems. The RMZ as defined here is not necessarily the same as setbacks or buffers. Setbacks are areas meant to protect an important feature (e.g., a stream or wetland) from certain types of adjacent activities, e.g., the area separating a building from the bank of a river. Setbacks are not typically designed to provide ecological function. On the other hand, buffers, which also protect important features, are commonly undeveloped, naturally vegetated areas that can contribute habitat and in the case of a stream, to riparian functions. In this document, we reserve the use of the term RMZ to mean the area capable of providing full function and managed to that end.

## 2.2 FOUNDATIONAL CONCEPTS IN RMZ DETERMINATIONS

### 2.2.1 *Desired Future Condition*

A major goal in fulfilling WDFW's mission to preserve, protect, and perpetuate Washington's fish, wildlife, and ecosystems is the protection and restoration of healthy, intact, and fully functioning riparian areas. More specifically, the goal will be achieved through management strategies that result in ecosystem composition and structure that provides the five key ecological functions associated with riparian ecosystems. A useful benchmark for this goal is desired future condition (DFC) for riparian areas. DFC describes what land managers are attempting to achieve, often in terms of composition and structure (e.g., vegetation or land-use), over a period of time in a given geographic area. The DFC we recommend results in fully functioning riparian ecosystems as measured by the five key ecological functions (bank stability, shade, pollution removal, contributions of detrital nutrients, and recruitment of large woody debris) in western Washington. The DFC for composition and structure is old, structurally complex conifer-dominant forest. Such forests exhibit large diameter trees, contain numerous large snags and logs, and have multi-layered canopies and canopy gaps, which promote understory plant diversity.

Throughout the Columbia Plateau, differences in hydrology and geomorphology manifest substantial site-level differences in composition and structure of riparian vegetation, and hence, the DFC for composition and structure is more site-dependent in the Columbia Plateau than in western Washington. Nonetheless, the DFC in the Columbia Plateau is based on the same concepts of ecosystem composition and structure that support the same five key ecological functions in forested regions; specifically, biologically diverse vegetation communities consisting of native trees,

shrubs, grasses and forbs. In addition, the DFC for the upland portion of the riparian ecosystem which serves as the zone of influence and contributes to the pollution removal function in the Columbia Plateau is often intact native shrub-steppe or prairie vegetation.

### 2.2.2 Site-Potential Tree Height (SPTH) Background

A fundamental component of our recommendation is the use of site-potential tree height (SPTH). In this section, we provide background information on its origin, applicability, and usefulness (see also Volume 1, Chapter 9).

In 1993, a group of experts (Forest Ecosystem Management Assessment Team [FEMAT]) was convened to develop a conceptual model to determine how to protect riparian areas in forested landscapes. This model has come to be known as the FEMAT curves (FEMAT 1993). Though this model is over 25 years old, it continues to be one of the most useful conceptual models informing riparian management.

The FEMAT curves provide a conceptual model of important riparian functions and how those functions change with increased distance from the stream channel (Figure 2.1). The model conveys two important points: (1) four of the five riparian ecosystem functions or processes occur within one 200-year SPTH; and (2) the marginal return for each function or process decreases as distance from the stream channel increases. Thus, designating a riparian area based on at least one SPTH<sub>200</sub> is a scientifically supported approach if the goal is to protect and maintain full function of the riparian ecosystem for aquatic habitat and species, including salmon.

The FEMAT curves and SPTH have been used to describe the lateral extent of riparian ecosystems, and accordingly, the width of the RMZ needed to provide full riparian ecosystem function.

**Figure 2.1.** The “FEMAT Curves” (FEMAT 1993): a generalized conceptual model describing contributions of key riparian ecosystem functions to aquatic ecosystems as the distance from a stream channel increases. “Tree height” refers to average height of the tallest dominant tree (200 years old or greater); referred to as site-potential tree height (SPTH).

FEMAT (1993, p. V-34) defined SPTH as “the average maximum height of the tallest dominant trees (200 years or more) for a given site class.” The key phrase in this definition is “200 years or more” which refers to the approximate minimum age of old-growth forests. This reflects FEMAT’s underlying assumption that old-growth forest conditions are needed for full riparian ecosystem functions. WDFW uses SPTH at 200 years (abbreviated SPTH<sub>200</sub>) in our recommendations in this Volume 2.

Given its utility, the height of site-potential trees has been described for a variety of tree species and can be readily found in silvicultural literature. Mean heights of dominant trees in riparian old-growth forest of Washington range from 100 to 240 feet (Fox 2003). The wide range of heights reflects differences in site productivity, i.e., local differences in soil nutrients and moisture, light and temperature regimes, and topography. Site productivity is described quantitatively through a site index, which is the average height that dominant trees of a species are expected to obtain at a specified tree age at a given location.

---

FEMAT defined Site potential tree height (SPTH) as “the average maximum height of the tallest dominant trees (200 years or more) for a given site class.”

“200 years or more” is the approximate minimum age of old-growth forests which are thought to be necessary for full riparian ecosystem functions.

---

### 2.2.3 *The Importance of Channel Migration Zones (CMZs)*

Not all streams have CMZs, but where CMZs are present, it is necessary to map the CMZ in order to establish an RMZ. The Washington Forest Practices Board Manual (DNR 2004) provides a useful definition of the CMZ as “the area where the active channel of a stream is prone to move and this results in a potential near-term loss of riparian function and associated habitat adjacent to the stream, except as modified by a permanent levee or dike” (DNR 2004, Section M2).

Protecting the CMZ from incompatible land uses (e.g., development) is important for providing riparian ecosystem functions. Human alterations to river channels that limit channel migration and bank erosion can degrade aquatic and riparian habitats. For these reasons, geomorphologists have developed protocols for delineating CMZs. Further, RMZ delineation along streams with CMZs ensures that riparian functions do not degrade as a channel moves. Proper delineation also helps landowners avoid siting homes and infrastructure in CMZs that coincide with geologically hazardous critical areas and floodplains ([WAC 365-190-120\[6f\]](#)).

### 2.2.4 *Relationship of CMZs and Floodplains*

This document does not include guidance on the integration of floodplains into RMZ delineation (see footnote 4 for a brief explanation about the active floodplain). However, a general understanding of floodplains and their relationship to CMZs is valuable, as the two often overlap.

Both federal and state regulations establish floodplain protections. Floodplain data and [maps](#) (typically 100-year floodplains) are readily available through the Federal Emergency Management Agency’s National Flood Insurance Management Program. Ecology is the state’s authority as lead on floodplain management and we support their recommendations for management of [Frequently Flooded Areas](#) (another type of critical area specified in GMA) and the use of the [Floodplains by Design](#) grant program to reduce hazards and restore natural functions. Proper floodplain delineation and protection helps landowners and land managers avoid placing homes and infrastructure in areas at high-risk of flooding.

The Bureau of Land Management provides common clues to help determine the presence of an active floodplain (BLM 2015) such as visual evidence of frequent inundation, which may include but is not limited to:

- Fresh deposits of fine sediment;
- Floodplain vegetation matted down or lying flat on floodplain from overbank flow or by deposition or overbank sediment;
- Debris piled on the upstream side of tree trunks; or
- High water marks seen on rocks, trees, or other stationary objects; and ice-rafted deposits on the floodplain.

However, BLM advises caution when relying on these visual clues. Furthermore, looking for signs that an active floodplain is present is only the first step toward delineating the outer edge of an active floodplain. We recommend reviewing BLM's technical reference titled *Proper Functioning Condition Assessment for Lotic Areas* (BLM 2015) and to consult Ecology for assistance regarding floodplain delineation and protections.

Good floodplain management is not only beneficial for human communities, it is also good for fish and wildlife. Although we do not describe use of the 100-year floodplain to measure the RMZ in Volume 2, we recommend that landowners and land use decision makers treat floodplains similarly to RMZs due to their importance to instream health, as habitat, and for their ecological services.

## 2.3 PROCEDURES FOR RMZ DELINEATION

To conserve riparian habitat, one must first establish the lateral extent (i.e., width) of the RMZ. In Chapter 1, we noted that an RMZ encompasses the riparian zone and zone of influence (Figure 2.2, page 16), and, where present, considers the CMZ (Figure 2.3, page 18). In this section, we outline general steps for collecting site-specific information essential to map an RMZ. These steps will help you identify a site's proximity to streams as well as essential site characteristics. With this information, we then explain how to delineate an RMZ.

In the rest of this section, we explain how to:

- Identify the ecoregion in which the riparian ecosystem is located (e.g., forested or dryland);
- Verify the presence of a stream;
- Identify the inner edge of the RMZ; and finally
- Determine the RMZ width.

### 2.3.1 *Determining Ecosystem Location*

We have identified two distinct types of ecoregions statewide, each with a slightly different RMZ delineation procedure: (1) Forested, and (2) Dryland. In general, forested ecoregions dominate western Washington, northeastern Washington, and portions of southeast, north central, and eastern Cascades. Dryland ecosystems are more readily contained in the Columbia Plateau Ecoregion east of the Cascade Range.

Landowners and land use planners should utilize the SPTH mapping tool, described in Appendix 1, to determine the ecoregion where the river or stream lies. Appendix 1 also provides instructions for using this tool to determine the 200-year site-potential tree height (SPTH<sub>200</sub>) at a given location.

### 2.3.2 *Verifying the Presence of a Stream*

Once you have identified which ecoregion you are in (e.g., Columbia Plateau), a qualified professional<sup>6</sup> should visit the site to verify the stream's location on or near the project area. It is very important not to rely solely on "stream maps" (e.g., DNR stream layer, National Hydrography Dataset) in place of a site visit (which is also important for mapping RMZs) because existing mapped stream layers often have errors, including streams whose locations are mapped inaccurately on the landscape, and streams actually present on the landscape that are missing from maps. Instead, use the site visit to validate existing stream maps.

### 2.3.3 *Identifying the Inner Edge of the RMZ*

Once you have verified a stream's location, proceed to locate the inner edge of the RMZ. Accurate RMZ delineation is dependent on using the correct starting point. In this section, we describe how to determine the location of the RMZ's inner edge using either the Channel Migration Zone (CMZ), if one is present; or the Ordinary High-Water Mark (OHWM). Ecology, as the state's water quality lead, provides extensive guidance and resources associated with OHWM or CMZ, and those resources are referenced here forward.

#### **2.3.3 (A) Identifying Ordinary High-Water Mark (OHWM)**

Delineate the RMZ's inner edge by identifying the OHWM along both sides of the stream following the procedure in Chapter 3 of Ecology's [OHWM delineation manual](#) (Anderson et al. 2016).

---

<sup>6</sup> Qualified professionals can be entities and individuals identified by the jurisdiction, WDFW regional habitat biologists, tribal biologists, Ecology staff, and/or other individuals familiar with stream verification and who have local expertise (e.g., Conservation District staff, Stream Teams, etc.).

**Figure 2.2.** The diagram depicts the *riparian management zone* (RMZ) for both forested (left) and dryland (right) ecoregions. The RMZ is coincident with the *riparian ecosystem*, which consists of the *riparian zone* (riparian vegetative community) and the *zone of influence*. The *riparian zone* extends from the edge of the active channel towards the uplands and it includes areas where vegetation is influenced at least periodically by flowing waters. The *zone of influence* includes areas where ecological processes significantly influence the stream, at least periodically.

### 2.3.3 (B) Identifying the Channel Migration Zone

Delineate the RMZ's inner edge by identifying the edge of the CMZ. Information about CMZs is available for certain streams in the state. For example:

- **SMA-Covered Shorelines** – During Shoreline Master Program comprehensive updates, many jurisdictions map the general location of CMZs associated with shorelines that fall under the jurisdiction of SMA (RCW [36.70A.480](#)). Note that even smaller streams not subject to SMA jurisdiction can have CMZs. In these cases, we recommend jurisdictions still identify and analyze CMZs to protect riparian ecosystems and public health and safety.
- **Puget Sound Streams** – The federal Endangered Species Act may require CMZ delineation in Puget Sound basin streams under the FEMA National Flood Insurance Program Biological Opinion for Puget Sound.

- **Other Local Examples** – Check with your jurisdiction to see if they have more detailed CMZ maps.

Ecology provides the following resources which can help landowners and land managers assess the presence and extent of CMZs where maps and data on CMZs do not currently exist:

- [CMZ Home Page](#) provides a high-level look at CMZ identification, and references useful documents;
- [Channel Migration Processes and Patterns in Western Washington](#) (Legg and Olson 2014) describes the general channel migration processes that occur in western Washington;
- [A Methodology for Delineating Planning-Level Channel Migration Zones](#) (Olson et al. 2014) provides a process for delineating “planning-level” CMZs and gives a few good examples in the appendices;
- [A Framework for Delineating Channel Migration Zones](#) (Rapp and Abbe 2003) is a more in-depth guide on how to develop “detailed” CMZs; and
- [Screening Tools for Identifying Migrating Stream Channels in Western Washington](#) (Legg and Olson 2015) outlines the “CHAMP” (channel migration potential) GIS layer with guidance on using it to identify high-risk CMZs.

**Figure 2.3.** This diagram depicts the spatial relationship between the riparian management zone (RMZ) and channel migration zone (CMZ) over time. As the active channel moves laterally within the CMZ, the riparian ecosystem moves with it. As a result, when considering the establishment of an RMZ, delineation should occur at the edge of the CMZ to account for the full extent of both the present day and future riparian ecosystems. Time 1 and Time 2 could be separated by days or centuries. This depiction of a forested system is one representation of a CMZ, which are also present in dryland systems: both should be managed for accordingly.

### 2.3.4 Determining RMZ Width

Once you have determined the location of the RMZ's inner edge, you then establish the width of the RMZ. The following stepwise process aims to establish recommended minimum delineation distances based on  $SPTH_{200}$ , vegetation composition, and pollution removal function (Figure 2.4). We say “recommended minimum” because upland adjacent land uses may require further adjustment of the RMZ to provide adequate pollution removal functions. Landowners and land use regulators should also consider additional actions to support wildlife connectivity and/or to protect riparian adjacent Priority Habitats.

**Figure 2.4.** Aerial view of variable width RMZ delineation process for forested (A) and dryland (B) systems.

- Step 1: Identify the  $SPTH$  or full extent of the riparian vegetative community (green);
- Step 2: Overlay a 100-foot pollution removal distance (yellow);
- Step 3: Delineate the RMZ (black) as the greater of the two distances.

We tailor the following guidance based on two types of ecoregion: (1) Forested and (2) Dryland.

#### 2.3.4 (A) Forested Ecoregions

Forested ecoregions are well-suited for using  $SPTH_{200}$  consistently to establish RMZ widths, and so for these areas, landowners and land managers can rely on the  $SPTH_{200}$  information provided in the  $SPTH$  mapping tool (see Appendix 1). The tool provides the derived average height attained by the dominant tree species at age 200 years ( $SPTH_{200}$ ) using the U.S. Natural Resource Conservation

Service (NRCS) forest productivity site index values, which we recommend for delineation of RMZs (see Sec 9.3 in [Volume 1](#) for background on the origin and use of SPTH<sub>200</sub>). In forested ecoregions, contributions of large wood as a riparian ecosystem function often define the farthest lateral extent of the RMZ.

Occasionally, the SPTH<sub>200</sub> may be less than 100 feet, in which case the pollution removal function (described in more detail in Section 2.3.5 below) defines the lateral extent of the RMZ.

In Washington, SPTH<sub>200</sub> can be as large as 260 feet: therefore, be sure to evaluate each soil polygon within 260 feet of the stream channel to ensure that RMZ delineation is in fact being driven by the largest dominant tree species.

#### **2.3.4 (B) Dryland Ecoregion**

Riparian ecosystems in arid and semi-arid regions of North America (also referred to as the dryland ecoregion) make up less than 1 to 3 percent of the landscape (Patten 1998). Dryland riparian ecosystems are hydrologically linked to and influenced by adjacent surface waters; as a result, surface waters sustain riparian vegetation that is clearly distinct from upland vegetation.

Riparian ecosystems in dryland environments are highly variable due to various site-level conditions. While these ecosystems may support large trees in low gradient floodplains, tree presence in riparian ecosystems throughout the dryland ecoregion is much more varied than in forested ecoregions, and so in many cases, the contribution of large wood no longer serves as the outermost ecological function for RMZ delineation. Further, riparian vegetation may be minimal or even non-existent, particularly along degraded, incised streams. In dryland ecoregions, the outermost of three factors drives delineation of the RMZ: (1) SPTH<sub>200</sub> (if trees are present); (2) riparian vegetative community; or (3) pollution removal function.

#### **2.3.4 (C) Considerations in Highly Modified and Urban Systems**

In some locations, riparian systems have been substantially modified, and current site-specific conditions may not provide adequate indication of where riparian vegetation would naturally occur. On the whole, this is particularly true of riparian systems in dryland ecoregions. In these instances, we recommend considering nearby sites with unaltered vegetation or selecting a representative site with similar bank height and gradient conditions to identify adequate riparian vegetation delineation for both protection and restoration.

---

### **Protecting Columbia Plateau's Priority Habitats Supports Riparian Health**

Native shrub-steppe vegetation and other drought-tolerant plant communities dominate Washington's dryland environments. Approximately 450 plant community associations occur in this region, with over 20% of these associations considered vulnerable (WDFW 2005, p. 523). Among the most imperiled ecosystems in North America, historical shrub-steppe has been greatly reduced due to conversion to other land uses (Vander Haegen 2007).

Riparian areas are critical to most animal species using shrub-steppe. Biodiversity in these vegetative communities increases dramatically where surface water occurs, and riparian areas directly support numerous species found only in or near water (Rogers et al. 1988, Johnson and O'Neil 2001). Linking and protecting upland adjacent Priority Habitat(s) not only aims to support Washington's wildlife and their associated habitat conservation goals, but also works to protect and maintain riparian ecosystem integrity.

---

Similarly, four major urban areas (Seattle, Spokane, Tacoma, and Bellingham) in forested ecoregions lack NRCS soils data. For these areas, WDFW identified nearby NRCS soils polygons and calculated weighted averages as estimates reflective of the surrounding environment (“imputed SPTH<sub>200</sub>”). Much like in forested areas where SPTH<sub>200</sub> data are available, we recommend using the imputed SPTH<sub>200</sub> values specified for each of these urban areas to delineate RMZs within them.

### 2.3.5 Width delineation steps

*Step 1: Use SPTH<sub>200</sub> if it is at least 100 feet.*

In **forested ecoregions**, WDFW recommends full protection within one SPTH<sub>200</sub>, identified with the use of our SPTH mapping tool (<https://arccg.is/1ueq0a>). The mean SPTH<sub>200</sub> in western Washington ranges from 100 to 240 feet (Fox 2003). Some soil polygons have SPTH<sub>200</sub> information for multiple tree species; therefore, each soil polygon within one SPTH<sub>200</sub> should be evaluated to ensure RMZ delineation is driven by the largest dominant tree species. Occasionally the SPTH<sub>200</sub> in forested ecoregions is less than 100 feet; for example, red alder is a fairly common riparian tree species, yet the SPTH<sub>200</sub> for this species does not always exceed 100 feet. If red alder is the only species for which SPTH<sub>200</sub> information is available for a certain location, and it is less than 100 feet, then skip to Step 3.

In **dryland ecoregions**, it is less common, but still possible to find riparian vegetation which includes—and may even be dominated by—large trees. Examples of large tree species in these areas are black cottonwood (*Populus trichocarpa*) and ponderosa pine (*Pinus ponderosa*). If SPTH<sub>200</sub> in dryland ecoregions exceeds 100 feet, then it should be used for the RMZ width.

*Step 2: In dryland ecoregions, if SPTH<sub>200</sub> is less than 100 feet or if no large trees are present, identify the extent of the riparian vegetative community.*

In **dryland ecoregions**, the riparian vegetative community is often comprised of shrubs, sedges, grasses, and forbs that are distinct from upland communities. For example, in the Columbia Plateau, vegetation within riparian ecosystems often exhibits an abrupt demarcation between the riparian zone and zone of influence. Phreatophytic<sup>7</sup> trees and shrubs and hydrophytic<sup>8</sup> herbaceous plants are confined to moist streamside areas, but the upland zone of influence may consist of sagebrush or bunchgrass communities [for more information, see Volume 1, Chapter 7 (Section 7.1.1)]. Where trees are not present or consist only of small species (less than 100 feet tall), WDFW recommends full protection of the entire riparian vegetative community. In some places the community may only be a few feet wide but in others it may extend up to several hundred feet, particularly when associated with a wetland or floodplain (Bermingham et al. 2013). Where the riparian vegetative community is less than 100 feet wide, go to step 3.

---

<sup>7</sup> A phreatophytic plant is a species that obtains water from the subsurface zone of saturation either directly or through the capillary fringe (Thomas 2014).

<sup>8</sup> Hydrophytic plants are those that are adapted to growing conditions associated with periodically saturated soils. They include obligate wetland plants that almost always occur in wetlands under natural conditions, facultative wetland plants that usually occur in wetlands but are occasionally found in non-wetlands, and facultative plants that are equally likely to occur in wetlands or non-wetlands (Lichvar et al. 2012).

### *Step 3: Overlay 100-foot pollution removal delineation*

The following applies to both **forested and dryland ecoregions**.

Our recommendation to protect full riparian function recognizes the importance of the pollution removal function of riparian ecosystems. Because pollution removal depends on multiple factors, including slope, soils, plant community composition, and upland uses, establishing a standard RMZ width for 100% pollution removal even at the site scale was impractical.

Where neither SPTH<sub>200</sub> nor the extent of the riparian vegetative community is at least 100 feet, we recommend RMZ delineation of a *minimum* distance of 100 feet, because this distance will achieve 95% or more removal efficacy of phosphorous, sediment, and most pesticides. To be clear, we value a similar removal efficacy for nitrogen, and at a 100-foot width, an RMZ would achieve only 80% removal efficacy for surface runoff containing excess nitrogen. However, the literature reflects that both the actual risk posed by excess nitrogen, as well as the efficacy of its removal, are very site-specific. In recognition of this, we strongly recommend that, where upland uses contribute nitrogen, the 100-foot minimum pollution removal distance be extended accordingly when determining the appropriate RMZ width.

Further, if RMZ widths are being based on a minimum pollution removal function at locations with steep slopes or poorly drained soils, distances greater than 100 feet should also be considered: this applies for all pollutants. Additionally, WDFW recommends cities and counties identify high intensity land uses that may be located adjacent to riparian areas within their jurisdiction and establish wider RMZs to enhance the pollution removal function in these locations as well, following guidance from Ecology.

When dealing with variables such as those outlined above, it may be necessary to seek expert assistance in determining the appropriate adjustments to RMZ widths based on the pollution removal function.

## CHAPTER 3. RIPARIAN REGULATORY PROTECTIONS

### 3.1 INTRODUCTION

This chapter gives guidance to help local governments review, develop, and implement regulatory tools to protect riparian ecosystems as critical areas, i.e., Fish and Wildlife Habitat Conservation Areas (FWHCAs). We describe key steps toward creating effective programs to protect riparian ecosystems consistent with the goals of the Growth Management Act (GMA), Shoreline Management Act (SMA), and Voluntary Stewardship Program (VSP). More specifically, this chapter describes recommendations for carrying out common land use activities and provides steps for developing Habitat Management Plans (HMPs). The riparian management zone (RMZ) should serve as the focal area to apply our recommendations.

Parcel-scale regulations are foundational to Washington's traditional land use regulatory approaches for protecting rivers and streams and their adjacent riparian ecosystem. However, sole reliance upon a regulatory approach at this site scale may result in loss of aquatic system function over the long term (see Volume 1). Thus, we believe that site-scale regulations must work in coordination with watershed-scale planning (Chapter 4) and that both should be monitored and adaptively managed (Chapter 5). In this chapter, we present considerations and recommendations for managing and protecting riparian ecosystems at both site- and watershed-scales.

### 3.2 RECOMMENDATIONS TO LOCAL JURISDICTIONS

Protection of watersheds commonly falls under the purview of agencies other than WDFW. Nonetheless, we encourage local jurisdictions (and their long-range planners in particular) to consider how land use patterns at all scales collectively affect fish and wildlife and other important ecosystem services.

The scientific literature review (see [Volume 1](#)) informs WDFW's position that protecting the area within one SPTH<sub>200</sub> from the edge of a stream channel maintains full riparian ecosystem functions for all aquatic species, including salmon, and promotes healthy, intact riparian ecosystems. This recommendation provides the greatest level of certainty that land use activities do not impair functions and values of riparian ecosystems. We recommend the use of monitoring and adaptive management (see Chapter 5) to inform regulations and evaluate the complement of both regulatory and voluntary conservation measures in achieving outcomes.

Land use decision makers should ensure all programs that can affect riparian habitat (e.g., CAOs; SMPs; and ordinances for clearing and grading, fire hazard reduction, and tree protection) are coordinated to optimize the ability of local policies, rules, and management activities to protect those habitats. Further, jurisdictions should look for gaps such as inconsistencies, exemptions and loopholes, or inefficient practices (e.g., inspection and monitoring protocols) that could impede protection of or cause harm to riparian ecosystems.

To that end, we provide important questions to consider when reviewing CAOs, Comprehensive Plans, or other plans that can affect riparian ecosystems:

**1. Conservation Strategies:**

- What external strategies exist (salmon recovery plans, reach-scale assessments, and incentive-based plans) to maintain, protect and restore riparian areas?
- Which of these strategies (if any) currently inform your regulatory, planning, and/or voluntary processes or programs?
- If these strategies are not in your current programs, could they be incorporated to provide additional benefits to riparian ecosystems? Are there other strategies that could also (or instead) benefit riparian ecosystems?
- Which of these strategies may help your jurisdiction satisfy mitigation obligations?
- How are riparian restoration and/or enhancement programs informed by these strategies?

**2. Regulatory Buffers:**

- Does your jurisdiction rely on  $SPTH_{200}$  for delineating regulatory riparian buffers?
- If your jurisdiction does not rely on  $SPTH_{200}$  for delineating those buffers, does your jurisdiction currently have regulatory buffers for riparian areas that are equal to or greater than the distance equal to  $SPTH_{200}$ ?
- Are there buffer exemptions? If so, how do those affect riparian function across your jurisdiction?
- Do your buffers consider the CMZ?
- Do your buffers consider adjacent wetlands and appropriate wetland delineation methodology as prescribed by Ecology?
- If your jurisdiction's CAO or SMP buffers are less than  $SPTH_{200}$ , can you use the RMZ to identify areas to do mitigation or areas impacted that will require mitigation?

**3. Restoration and Adaptive Management (see also Chapter 5):**

- Can your jurisdiction use the RMZ to identify areas for incentive-based restoration?
- Do you have a monitoring and adaptive management program for improving permit implementation?
- Is your jurisdiction collecting information on effectiveness of protecting riparian areas?
- If you collect effectiveness information, what programs (e.g., incentives, regulations) could you improve to increase riparian conservation?

**4. Other Programs and Regulations**

- What other regulations separate from CAOs, may inadvertently affect riparian areas? (e.g., clearing and grading ordinance that lack safeguards for riparian protection.)
- Are there opportunities to connect riparian areas with other protected areas (e.g., frequently flooded areas, geologically hazardous areas, green belts, parks, wetlands, and aquifer recharge areas)?

**3.2.1 Recommendations for Common Activities in the RMZ**

Local governments should regulate all land use activities that are likely to impact functions of a riparian ecosystem found within the RMZ to ensure, at a minimum, that the existing functions and values are protected from development actions. For the purposes of meeting requirements under GMA, SMA, and VSP, we describe the RMZ as the area in which functions and values are contributed

to the riparian ecosystem: providing a delineated space not just for protection, but also for mitigation and management. We also recommend prioritizing the RMZ as the space for restoration<sup>9</sup>. We provide specific information and recommendations for the following ten common activities: (Note that neither the list of activities nor the recommendations themselves are exhaustive; for more information, contact your WDFW regional habitat biologist.)

1. On-site Sewage Systems (OSS)
  2. Bank hardening
  3. Clearing, grading, and placement of fill
  4. Removal of noxious weeds
  5. Forest practices and conversions
  6. Firewise and wildfire hazard reduction
  7. Removal of hazard trees
  8. Non-compensatory restoration and enhancement
  9. Emergency activities
  10. Educational or Recreational Areas
1. *On-site Sewage Systems (OSS)* – Historically, developers sited OSS at lower elevations bordering streams, lakes and wetlands in order to use passive gravity flow. The disadvantage of these systems is that when drain fields are located near water features, they can more easily contaminate water with high loads of nutrients and toxic pollutants, causing significant impacts to flora, fauna and water quality. The State Department of Health adopted rules establishing public health standards for location, design, installation, operation, maintenance, and monitoring of OSS, including requiring setbacks from waterbodies ([WAC 246-272A](#)) which modern OSS systems, using pump systems, can support. Some OSS may meet public health standards even if located within RMZs; nevertheless, jurisdictions should exercise authority to require HMPs to ensure project proponents protect habitat functions of riparian critical areas.
  2. *Bank Hardening* – We recommend jurisdictions avoid allowing new development that requires bank protection now or is likely to in the future (consider channel migration, wind and wave action, and climate change), unless it addresses an imminent threat as an emergency activity (see Emergency Activities in this section below). Always look to alternative places to site a project so that no bank protection measures are needed. If measures cannot be avoided, require that a project proponent evaluate the effectiveness of bioengineering alternatives (also known as soft armoring) prior to proposing hard armoring. Follow bank protection recommendations in the [Washington State Integrated Streambank Protection Guidelines](#) (Cramer et al. 2002) when bank protection is unavoidable.
  3. *Clearing, Grading, and Filling* – We recommend jurisdictions acknowledge impacts of clearing, grading, and filling on riparian areas in their CAOs by limiting these activities to areas outside the RMZ (unless directly related to restoration) as they can negatively affect riparian areas. If a clearing, grading, or filling project must encroach in an RMZ, limit disturbance and minimize

---

<sup>9</sup> As explained previously, many riparian areas had already experienced a substantial degree of degradation before laws like GMA, SMA, and VSP were passed, so while protecting what level of riparian functions and values remain is essential, protection alone will not be sufficient for meeting the needs of the state's fish and wildlife species.

effects to the greatest extent possible. Require that a qualified professional prepare an HMP describing how the project proponent will follow the mitigation sequence.

Jurisdictions that exempt small areas from filling or grading ordinances in riparian ecosystems should calculate cumulative impacts from these exemptions. They should also mitigate impacts and subsequently establish monitoring to ensure that mitigation measures are effectively negating potential losses to habitat function.

4. *Invasive and/or Noxious Plant Removal* – Many CAOs do not require a permit for control and removal of invasive and/or noxious weeds within riparian ecosystem. We support this when weed control efforts (1) employ hand weeding with light equipment; (2) use only Ecology-approved aquatic herbicides and adjuvants (a substance added to herbicides to improve application); avoid use of hazardous substances; and (3) do not result in soil compaction. Local governments should retain some oversight authority for more extensive invasive and/or noxious plant control projects to ensure adequate protections of riparian functions, especially water quality. Most communities issue an exemption letter or permit, which should include conditions to ensure impacts to fish, wildlife, and habitat are minimal.

It is important to note that even plants native to the region can, in certain circumstances, be detrimental to riparian areas. An example is in Puget Sound Prairies, where in the absence of periodic fire events (typically prescribed fire), common western Washington conifer species like Douglas fir outcompete native deciduous species (primarily Oregon white oak). In these circumstances, conifer removal and re-establishment of historical riparian conditions (oak and prairie vegetation) should occur under an approved HMP. WDFW regional [habitat biologists](#) can assist in preparing, reviewing, and implementing such a plan.

5. *Forest Practices and Conversions* – The state’s Forest Practices Act ([RCW 76.09](#) and [WAC 222](#)) regulates forest practice activities on forestland: We recommend that the proponent always contact DNR prior to conducting forest practice activities and seek technical assistance from a WDFW regional habitat biologist to ensure protections for Priority Habitats and Species. When conducting commercial forest practice activities, the forest practice rules—not the CAO—apply for protection of resources on site. Lands converted from forestry to another use require a special forest practice permit, and when converting land, local CAOs are applied. If conversion occurs, WDFW recommends timber harvests not be allowed within SPTH<sub>200</sub>.
6. *Wildfire Hazard Reduction* – Wildfire is a concern in Washington, though the threat varies across the state. Local regulations to reduce wildfire hazards should be coordinated with a Firewise program in order to require landowners to consult with a Firewise professional (<http://www.dnr.wa.gov/firewise>) before removing trees or manipulating vegetation in an RMZ. Understanding the composition of historical forest stands and shrub-steppe can help ensure retention of riparian functions when carrying out wildfire hazard reduction activities. When fuel (vegetation) reduction efforts involve the removal of merchantable trees, the proponent should check with the local jurisdiction and DNR, which may require a permit for tree removal.
7. *Removing Hazard Trees* – Tree trimming or removal in RMZs is sometimes necessary to address public safety concerns but should be balanced with the potential impacts to riparian ecosystem function. Jurisdictions should define a “hazard tree” (sometimes referred to as a “danger tree”) as a threat to life, property or public safety, and require that the method of tree removal not

adversely affect riparian ecosystem functions if possible. Specifically, we recommend that any removal of hazard trees involve an avoidance and minimization of damage to remaining trees and vegetation within the RMZ. We further recommend that local governments require a qualified arborist to evaluate requests for hazard tree removal. The qualified arborist should be able to establish when a tree presents an imminent threat to life, property or public safety.

It is important to note that snags (dead trees) are a Priority Habitat feature for wildlife, and so should be preserved if not hazardous.

Some local governments use Forest Practice Rules ([WAC 222-21-010\[4\]](#)), which define a hazard tree as “any qualifying timber reasonably perceived to pose an imminent danger to life or improved property.” This applies to any tree within 1.5 tree-lengths of the structure. A DNR forester can verify during a site visit that a tree is a hazard based on this definition, and thus removing the hazard would not be subject to the Forest Practice jurisdiction or require a Forest Practice Application.

8. *Restoration and Enhancement* – We encourage local governments to include in their CAOs allowances for restoration and/or enhancement of the riparian ecosystem, including in-channel or streamside work, especially on lands set aside for conservation. To the extent possible, jurisdictions should promote incentives and set up a streamlined review process for restoration or enhancement projects to help facilitate project proponents not just meeting the minimum requirements of the local CAO, but instead going “above and beyond”. Significant resources are available to jurisdictions that address limiting factors in riparian areas or undertake high priority restoration activities that benefit salmon or other listed species (*see Chapter 4 for information on restoration*).
9. *Emergency Activities* – Local codes typically have provisions for emergency activities (e.g., bank stabilization to address imminent threats to homes) that provide relief from time delays related to procedural code requirements. Local regulations should distinguish the immediate need to permit an emergency activity from the need to compensate for its impacts after-the-fact.
10. *Educational or Recreational Areas* – Public access to shorelines is a priority use under the SMA and providing educational and/or recreational developments such as trails, viewing platforms, or similar facilities may also enhance the public’s understanding and appreciation of riparian areas, streams, and habitats. Thus, some focused use of the RMZ for educational and recreational activities may be desirable, if it does not create significant disturbances. Most CAOs include allowances for unpaved access to a stream for aesthetic or recreational enjoyment with defined limits on clearing to avoid impacts and minimizing soil, vegetation, and habitat disturbances: this is an allowance we support. That said, construction of trails could allow greater access for pets and other high intensity recreation, which may increase predation on, and/or disturbance of fish and wildlife species. Regulations should minimize impacts from recreational trails and interpretive facilities to the extent practicable, informed by PHS data and associated management recommendations.

### 3.2.2 *Project-specific Riparian Habitat Management Plans*

When reviewing proposed projects near streams, local governments typically require applicants to provide detailed site-specific HMPs (often called a Critical Area Report). Here we describe six aspects of Riparian HMPs that we recommend be addressed in CAOs:

1. When HMPs are required;
  2. Which additional critical areas must be delineated, and how;
  3. Which specific land use actions must be identified, and how;
  4. Mitigation requirements;
  5. Monitoring and Adaptive Management requirements; and
  6. Articulate who must prepare and review the HMP.
1. *When required* – We recommend jurisdictions require an HMP whenever someone proposes a land use activity in an RMZ (regardless of the jurisdiction’s regulatory RMZ delineation) or when a proposal likely could affect riparian or aquatic functions. In cases where there is less confidence in the spatial accuracy of the RMZ, consider requiring a Riparian HMP when impacts occur adjacent to the RMZ’s zone of influence.
- Maps, [DNR’s stream layers](#), the [National Hydrography Dataset](#) (NHD), and other (e.g., local) stream layers are important for triggering HMPs. An HMP should be required whenever a stream is present near proposed development activities, including but not limited to subdivisions (plats, short plats, and large lot subdivisions), land/vegetation disturbing activities (e.g., clearing and grading, septic drain field siting), and stormwater routing.
2. *Critical Area Delineation* – HMPs should have the extent of critical areas within and adjacent to a proposed project site identified, along with ecosystem functions that need protection. Follow the RMZ delineation procedure outlined in Chapter 2, along with locations of other critical areas on or near the site (e.g., wetlands, geologic hazards, frequently flooded, critical aquifer recharge areas; informed by Ecology). Also, identify salmon and other priority aquatic species that use the stream network in the immediate vicinity as well as up- and downstream. Likewise, HMPs should identify Priority Species that may use the riparian corridor and any other Priority Habitats to which the corridor is connected. Attach the delineation map (1) to the property’s title to inform future property owners of the site’s critical areas, and (2) use it to update the jurisdiction’s critical areas maps.
3. *Land Use Action Identification* – A complete HMP should describe relevant management recommendations for Priority Habitats and Species found on or near the site. Include a map in the HMP showing the location of proposed land use actions. It should identify and quantify current and proposed disturbances to the RMZ and other FWHCAs.
4. *Mitigation* – The HMP should have a description of the project proponent’s mitigation sequencing. It should describe in detail measures to avoid impacts and minimize unavoidable impacts (e.g., clustering, conservation easements, and seasonal construction restrictions). If mitigation or compensation is necessary, the HMP should identify ways to improve riparian ecosystem function by enhancing riparian corridor connectivity (e.g., removal of stream barriers) or by improving the quality of the riparian area (e.g., replacing invasive vegetation with appropriate native vegetation).
5. *Monitoring and Adaptive Management* – The HMP should describe requirements for monitoring and adaptive management. In addition, it should identify measurable standards and expectations to monitor compliance (e.g., areal extent of vegetative cover, composition of riparian tree species, maximum invasive plant cover). The HMP should identify frequency of visits to monitor the site (e.g., at year 1, 2, 3, 5, 8, and 10) as well as measurable triggers for requiring more actions (e.g., maximum percent area coverage of invasive plants). The HMP

should specify who is responsible for preparing, reviewing, and submitting reports. Finally, if deemed necessary by the jurisdiction, the report should include a cost estimate for monitoring, and the project proponent should post a bond for this amount or more to allow for overages.

6. *Preparer and Reviewer* – A qualified professional biologist, botanist, or ecologist should prepare the HMP; additional expertise related to CMZs, unstable slopes, and wetlands may also be necessary. Additionally, an independent professional with similar qualifications should review the HMP. WDFW's regional habitat biologists can often serve in this role, especially for larger projects. USFWS or NOAA Fisheries should also review the HMP if the project might affect a federally listed fish or wildlife species.

### 3.3 RIPARIAN MANAGEMENT IN URBAN AREAS

Some people have raised questions about the applicability of RMZs to urban and urbanizing areas. These concerns generally fall into two categories: (1) the science on RMZs comes largely from agricultural and forestry settings, and so is perceived to be irrelevant to urban areas; and (2) there is a belief that the need to maximize density of development in urban areas is in direct conflict with the protection of riparian areas.

Concerns over the relevancy of literature on riparian functions to urban areas is largely unfounded. While most riparian ecosystem studies are from non-urban settings, the principles are the same. Functions of shade, bank stability, large wood recruitment, nutrient inputs, and pollutant removal operate similarly in urban areas as they do in other settings. However, within urban areas, these riparian ecosystem functions are often greatly diminished or even absent altogether.

The role that urban RMZs play in delivering habitat functions for aquatic and many terrestrial species is also like that in non-urban areas. Factors that may be different in urban areas are that urban riparian ecosystems may perform some functions at reduced levels due to their position in developed watersheds, which are often heavily degraded. However, intact RMZs in urban areas function as wildlife corridors that link habitat patches, which is critical for many species. In fact, sometimes RMZs in urban areas may be more important from a habitat standpoint, because within urban areas, adjacent uplands are often even more degraded than the RMZs, which then are often the only remaining areas where habitat functions are provided. Thus, a key element to maintain in urban RMZs is connectivity, both in and along streams.

Many Puget Sound salmon move through channelized streams, traversing heavily urbanized areas prior to reaching spawning grounds and as juveniles on a reciprocal journey to marine waters. Salmon must pass through a wide spectrum of development. For example, adults returning to spawn often start in urban cores (e.g., downtown Seattle), where streams are often channelized; then pass through areas with small lots and high urban density and into suburban creeks where larger lots allow for more riparian protection; and finally, to rural lots with less development and better ecosystem health. When juveniles make their journeys in reverse, they generally spending more time in each of these areas than their parents did, and yet because of their small size, they are also at much greater risk of not surviving any of them. While the decades-long decline of many of our native salmon stocks illustrate just how challenging this is, their persistence—especially the subspecies which are showing signs of improvement—shows us what is possible. Therefore, it is critical that the urban environment maintain and enhance the ability of different species and ages of salmon to not just survive, but thrive, while in these disturbed areas.

Many of the actions we recommend urban communities focus on are the same or similar to those appropriate in less densely developed areas. For example, it is critical to maintain connectivity through properly sized culverts such that all fish can pass through at all relevant life stages. Additional riparian function can be achieved through revegetation efforts using native plants and by improving connectivity between habitat patches. A landscape analysis can help identify existing connections to protect, as well as areas where restoring connectivity is a priority. On the other hand, some actions are particularly well-suited to urban jurisdictions, like standards for Low Impact Development (LID) and state-of-the-art stormwater management. Further, when changes are made to urban infrastructure, this may create opportunities to improve riparian functions while contributing to new or improved public open spaces.

Recommendations for urban riparian ecosystems:

1. Delineate urban RMZs to protect what areas remain and to highlight lost or degraded areas to target for restoration.
2. Quantify current conditions, with a goal of maintaining and improving functions through regulatory and voluntary means.
3. Identify and prioritize restoration opportunities and projects within the RMZ:
  - a. Protect riparian functions that remain, especially in places that are relatively high functioning; implement actions that enhance degraded functions (*see* Chapter 4).
  - b. Prioritize opportunities to maintain and restore in-stream and riparian connectivity.
  - c. Adopt a stormwater design manual equivalent to Ecology's most current manual for western and eastern Washington.
  - d. Manage stormwater by adopting Ecology's latest manual regarding LID for new development, redevelopment and retrofit projects.
4. When replacing or removing existing infrastructure within an RMZ:
  - a. Map RMZ to pinpoint the best sites to restore – consider connectivity and adjacency to other Priority Habitats;
  - b. Improve aquatic connectivity by replacing culverts and removing barriers to movement;
  - c. Revegetate with native plants and consider improvements for wildlife by integrating structures necessary for nesting, breeding, and foraging;
  - d. As infrastructure is remodeled or replaced, incorporate additional setbacks from streams;
  - e. Control access to RMZ to limit soil compaction;
  - f. Avoid operating equipment near the stream to reduce sedimentation and soil compaction; and
  - g. Avoid using chemicals in the RMZ which are not approved for use there by Ecology.

### 3.4 MANAGING WATERSHEDS

As described in Chapter 8 of Volume 1, land use activities in a watershed can affect the stream network, even when the riparian ecosystem itself is relatively undisturbed. "Watershed management" is a land management approach that seeks to minimize negative effects of upland land uses on aquatic systems, which include riparian areas. The remainder of this chapter focuses on key watershed elements important to managing and protecting functional aquatic systems. Many of the approaches we outline here are non-regulatory and can complement regulatory efforts;

as previously stated, we recommend cities and counties inventory current conditions of critical areas and, based on that inventory, develop watershed scale management plans accordingly.

Fully functional riparian ecosystems, in combination with targeted watershed protections, provide significant benefits to humans. These benefits, often described as ecosystem goods and services, include clean water; decreased flooding; increased nutrient cycling, sediment and pollutant filtering; reduced erosion; carbon sequestration; and cultural services such as recreational, spiritual, and other nonmaterial benefits. These services provide real but often unquantified economic benefits to individuals and society that largely go unnoticed until they are lacking.

### 3.4.1 *Watershed-Scale Recommendations to Protect Aquatic Systems*

To achieve desired ecosystem goods and services watershed managers should focus on influencing watershed processes that act upon water, wood, sediment, nutrients, vegetation, and pollutants at both the site- and watershed-scale. This section focuses on watershed-scale management.

*Restore and Protect Watershed Processes* – Efforts to improve watershed conditions should first focus on protecting and restoring watershed *processes* (e.g., natural disturbances) that create and retain habitat for fish and wildlife. Maintain the frequencies, magnitudes, and durations of natural disturbances (flood and fire being the most common) to the greatest extent that surrounding land uses can tolerate.

*Manage Land for Stormwater* – Stormwater runoff can change the timing, quality, and quantity of water provided to streams. Land uses should avoid/minimize changes to surface water flows. Protection and restoration efforts should focus on attenuating peak flows and reducing pollutants. Primary tools available to local governments include land use designations/zoning code, and stormwater regulations. See [City of Redmond Watershed Management Plan](#) (City of Redmond 2013).

*Manage Land for Stream Temperatures* – Reduced riparian vegetation cover, decreased streamflow, and simplified stream channels (e.g., increased width-to-depth ratio and reduced groundwater exchange) can lead to increased water temperature (Volume 1, Chapter 4). Modifications like these are often the result of land use activities such as riparian vegetation removal; water diversions; unmanaged livestock grazing; and stream channelization associated with roads, levees, and other forms of development. Identify and restore thermally sensitive stream reaches at the watershed scale to maintain optimal stream temperatures for sensitive aquatic species such as salmonids.

*Restore and Protect Connectivity* – Manage watersheds to avoid creating longitudinal (e.g., dams, road crossings), lateral (e.g., levees and roads/buildings that cutoff riparian areas and floodplains from their stream), and vertical (water withdrawals, reductions of floodplains) barriers to fish and wildlife movement and fragmentation of their habitat. This is especially important for highly mobile species that require a variety of habitat components across large areas. For example, where CMZs interact with floodplains, dikes and levees restrict the movement of the river or stream and also serve as a barrier for fish and many forms of wildlife.

Restoration to correct existing barriers to movement of water, wood, sediment, and species (e.g., removing blocking culverts) is a high priority with proven benefits for salmon. Connectivity to achieve nearly or completely contiguous RMZs is important to water quality and to achieve

connectivity among patches. Ensuring connectivity both for terrestrial and aquatic wildlife works towards a more interconnected and healthy riparian system.

*Plan for Climate Change* – Impending changes to aquatic systems caused by climate change increases risk to species already threatened, and riparian ecosystem protection is one of the most useful responses to ameliorate those risks. For example, because more intense rainfall events will lead to wider streams, larger culverts will be necessary to support fish passage. WDFW, in collaboration with the University of Washington’s Climate Impacts Group, created an [online tool](#) (UWCIG 2017) that estimates how much a stream’s channel width will increase with climate change in the years 2040 and 2080. Connectivity within the RMZ allows voluntary migration for species and helps minimize temperature change and increase off-channel storage of water to reduce low flows.

*Conduct Monitoring and Adaptive Management* – Monitoring and adaptive management are important elements to both site-scale and watershed-scale; this is addressed further in Chapter 5.

### 3.4.2 *Tools and Key References for Assessing Current Watershed Conditions*

Washington’s State agencies, including WDFW, have developed multiple tools to assist local government in assessing watershed conditions. Jurisdictions can utilize these resources—many available at no cost—to quantify changes in land cover, tailor planning for specific species, coordinate monitoring activities, inform restoration, and assess watershed health.

WDFW’s High Resolution Change Detection (HRCd) is a spatial dataset that characterizes changes in land cover. This tool allows jurisdictions to evaluate in specific ways how watersheds are changing at a sub-parcel scale over 2- to 3-year intervals. This dataset is currently available throughout the entire Puget Sound basin and in some Eastern Washington watersheds. HRCd data is available at [www.pshrcd.com](http://www.pshrcd.com).

WDFW’s [Priority Habitats and Species](#) program has several resources of interest to watershed planners. In addition to this two-volume document on riparian ecosystems, readers will find useful ideas in [Land Use Planning for Salmon, Steelhead and Trout: A land use planner’s guide to salmonid habitat protection and recovery](#) (Knight 2009) and [Landscape Planning for Washington’s Wildlife: Managing for Biodiversity in Developing Areas](#) (Azerrad et al. 2009).

Since 2004, the [Pacific Northwest Aquatic Monitoring Partnership](#) has collaborated with West Coast federal, state, and tribal agencies to coordinate monitoring activities and develop common approaches. This partnership provides best practices, mapping tools, and protocols, and serves as a voluntary clearinghouse for a wide variety of monitoring projects.

Since 2009, Ecology’s [Watershed Health Monitoring Project](#) has been monitoring sites throughout the state to assess watershed health. This project’s protocols can be adapted by jurisdictions and scaled to watersheds of various sizes. Data is stored in the [Environmental Information Management database](#). This sophisticated database allows users to input and retrieve data via the web, reliably store it, and make it available for analysis. Quality assurance/quality control measures ensure data put into the database are of high quality.

Ecology’s [Puget Sound Watershed Characterization](#) is a Puget Sound-wide tool that compares areas based on their suitability and value for restoration and protection. This tool informs two fundamental questions: (1) where to focus protection and restoration on the landscape first, and

(2) what types of activities and actions (i.e., restoration, protection, conservation, or development) are most appropriate to that place. With insights gained by this tool, decision-makers can incorporate information regarding watershed processes to improve plans (e.g., comprehensive plans, subarea plans, CAOs, stormwater plans) and conservation efforts (e.g., in-lieu fee programs, open space tax credits, open space land acquisitions).

In 2016, the Washington Department of Commerce (Commerce) published [Building Cities in the Rain](#) (Ballash 2016) to help communities improve watersheds while redeveloping and revitalizing urban areas. The guidance describes an optional three-step process for prioritizing watersheds for stormwater retrofits in urban areas. Commerce's [Puget Sound Mapping Project](#) uses an interactive map to help users develop insights about how current and expected development patterns might affect the region's environmental health. The tool is designed to help decision makers consider information from the Puget Sound Watershed Characterization (described above) when making decisions regarding development projects, urban growth boundaries, and compensatory mitigation.

Finally, the University of Washington's [Climate Impacts Group](#) has developed a suite of tools, many in concert with WDFW, which may be useful for landowners and land use decision makers including climate trends, culvert design projections, and habitat connectivity.

# CHAPTER 4. RESTORING RIPARIAN ECOSYSTEMS

## 4.1 INTRODUCTION

This chapter provides high-level guidance to landowners, land use decision makers, and conservation partners to promote restoration of riparian areas. Despite recent efforts to protect existing riparian systems, imperiled salmon stocks and other riparian dependent endangered species are not recovering as hoped (Table 4.1). Since non-indigenous settlement of Washington began in the 1800s, between 50 percent and 90 percent of riparian ecosystems have been lost or extensively modified (RCO 2019). While two subspecies (Hood Canal summer chum and Snake River fall Chinook) are moving towards recovery, most listed salmon in Washington are below recovery goals (Table 4.1).

The lack of recovery is also evidenced in the ongoing decline of salmon fishing, which affects the long-term health of Washington's tribes, Washington's economy, and our shared cultural heritage. The lack of salmon is one of the primary reasons Southern Resident Killer Whales are at risk of extinction, in addition to other impacts such as vessel disturbance and pollutants. (Lacy et al. 2017, Murray et al. 2019)

Given the extent of historical loss, WDFW recognizes that protection alone of remaining riparian ecosystems, will not recover salmon or the Southern Resident Killer Whale population. Therefore, WDFW recommends restoring and enhancing riparian ecosystems to achieve healthy, intact, and fully functioning riparian systems statewide. Continued investments in restoration will be required at all levels of government and in concert with Washington tribes.

**Table 4.1.** Non-statistical evaluation of natural origin (wild) fish that returned to spawn with consideration for threats and factors affecting health including habitat, harvest, and hydropower. (Adapted from RCO 2019; Data sources: WDFW, Indian tribes, NOAA).

| Below Goal<br>(Endangered Species Act-Listed Salmon in Washington) |                                     |                                | Near Goal                |
|--------------------------------------------------------------------|-------------------------------------|--------------------------------|--------------------------|
| Getting Worse                                                      | Not Making Progress                 | Showing Signs of Progress      | Approaching Goal         |
| Upper Columbia River Spring Chinook                                | Upper Columbia River Steelhead      | Mid-Columbia River Steelhead   | Hood Canal Summer Chum   |
| Puget Sound Chinook                                                | Lower Columbia River Chum           | Lake Ozette Sockeye            | Snake River Fall Chinook |
|                                                                    | Lower Columbia River Coho           | Lower Columbia River Steelhead |                          |
|                                                                    | Lower Columbia River Fall Chinook   | Snake River Steelhead          |                          |
|                                                                    | Lower Columbia River Spring Chinook | Puget Sound Steelhead          |                          |
|                                                                    | Snake River Spring Chinook          |                                |                          |
|                                                                    | Snake River Summer Chinook          |                                |                          |

## 4.2 RESTORATION ACTIONS

Although this section focuses on restoring riparian areas for the benefit of salmon, emulating historical conditions benefits many other aquatic and terrestrial species as well. WDFW is available to provide technical assistance and species-specific guidance for terrestrial species-focused restoration and recovery efforts. To recover salmon, we must protect all remaining existing riparian and watershed functions, while seeking opportunities to restore functions that have been lost over time. We provide the following information to assist the restoration community<sup>10</sup> in understanding what is important to restore.

### 4.2.1 *Developing a Restoration Strategy*

Aquatic restoration strategies typically start with a clear set of goals and objectives. The selection of appropriate restoration strategies is informed by the political, social, and ecological context of the watershed, and bounded by the extent of opportunities and constraints. It is important in ecosystem restoration to consider the habitat attributes and scale necessary for a desired suite of species, be they aquatic or terrestrial. At a watershed scale, restoration efforts should focus first on projects that offer the greatest potential for success. The [Stream Habitat Restoration Guidelines](#) (Cramer 2012) suggest the following prioritization of stream habitat restoration strategies that are specific to instream related activities most often geared at anadromous fish:

1. *Protect existing habitat.* Protect areas that provide healthy, high-quality habitat functions (strongholds, refugia, and key sub-watersheds) to prevent further degradation. Secure, expand, and link protected areas.
2. *Connect habitat.* Connect and provide access to isolated habitat, including instream, off-channel, and estuarine habitat made inaccessible by culverts, levees, fragmentation, or other man-made obstructions.
3. *Restore habitat-forming processes.* Employ land use recovery and watershed restoration techniques to restore processes that create, maintain, and connect habitats (including restoring sediment dynamics, large wood dynamics, and flow regimes; avoiding/removing manmade disturbances within the riparian ecosystem; and maintaining water quality, floodplain connectivity, and channel evolutionary processes). Employ a combination of active or passive restoration techniques, as necessary. Active restoration involves accelerating processes or attempting to change the trajectory of succession; passive restoration simply involves ceasing environmental stressors such as agriculture, grazing, or timber harvest, and then allowing nature to take its course.
4. *Create new or enhance existing habitat.* Improve existing or create new habitat for specific species by installing instream structures such as large woody debris; reconfiguring channel shape, cross-section, or profile to reduce incision or restore flow; or constructing one or more new side channels.

In conjunction with other state agencies and partners, WDFW provides multiple technical guidance documents to help design and implement riparian restoration projects that have proven successful

---

<sup>10</sup> Many watersheds in Washington have salmon recovery restoration goals that can be obtained from regional Salmon Recovery Boards or Lead Entities for Salmon Recovery. Lead Entities and Salmon Recovery Boards are in every region of the state, including those areas without salmon or other anadromous fish ([https://www.rco.wa.gov/salmon\\_recovery/regions/regional\\_orgs.shtml](https://www.rco.wa.gov/salmon_recovery/regions/regional_orgs.shtml)).

in different types of landscapes, including on marine shorelines, and on river- and streambanks. These are part of a suite of Aquatic Habitat Guidelines found at <https://wdfw.wa.gov/licenses/environmental/hpa/application/assistance>. They include:

- [Water Crossing Design Guidelines](#) (Barnard et al. 2013)
- [Stream Habitat Restoration Guidelines](#) (Cramer 2012)
- [Integrated Streambank Protection Guidelines](#) (Cramer et al. 2012)
- [Land Use Planning for Salmon, Steelhead and Trout: A land use planner's guide to salmonid habitat protection and recovery](#) (Knight 2009)
- [Draft Fishway Guidelines for Washington State](#) (Bates 2000)
- [Draft Fish Protection Screen Guidelines for Washington State](#) (Nordlund and Bates 2000)
- [Marine Shoreline Design Guidelines](#) (Johannessen et al. 2014)
- [Your Marine Waterfront](#) (WDFW 2016)
- [Protecting Nearshore Habitat and Functions in Puget Sound](#) (AHGP 2010)

### 4.3 IMPLEMENTING RIPARIAN STRATEGIES THROUGH INCENTIVES

There are several types of conservation incentives available to individuals and local governments:

- *Financial assistance*: grant programs that provide funding for conservation activities
- *Tax adjustment*: tax reductions for landowners undertaking conservation activities
- *Technical assistance*: advice and/or hands-on help for landowners on tools or techniques
- *Recognition*: promotion of landowners who undertake conservation actions

Each of these will be described (and examples provided) in more detail, below.

#### 4.3.1 *Financial Assistance*

State and federal grant funds are available for riparian ecosystem conservation and restoration projects on public and private lands through the Recreation and Conservation Office (RCO) and Salmon Recovery Funding Board. To access these funds and to learn more, go to <https://www.rco.wa.gov/grants/index.shtml>. Grant programs include:

- [Aquatic Lands Enhancement Account](#)
- [Washington Wildlife and Recreation Program](#) (WWRP; Riparian Protection, Critical Habitat, Natural Areas, and Urban Wildlife Habitat Categories)
- [Salmon Recovery Funding Board](#)
- [Estuary and Salmon Restoration Program](#)—a program of WDFW
- [Land and Water Conservation Fund](#)
- [Puget Sound Acquisition and Restoration](#)

Land trusts also help land owners conserve habitat for key aquatic and terrestrial species, often leveraging funds from foundations and other non-governmental sources; see [www.walandtrusts.org](http://www.walandtrusts.org) for a county-specific list of land trusts.

For agricultural property owners, local conservation districts and the Washington State Conservation Commission (WSCC) can provide technical assistance to find an approach that works for the farmer and improves riparian ecosystem function. Technical assistance is also available

from the federal Natural Resources Conservation Service (NRCS), Washington State University Extension, and WDFW. Additionally, a host of state and federal financial incentives to expand and maintain riparian functions within the riparian management zone (RMZ) are available, some of which are listed below. For example, the Conservation Reserve Enhancement Program (CREP) provides funding to landowners for riparian preservation and is the most successful riparian buffer program in Washington. Since CREP's 1999 inception in our state, more than 900 miles of stream buffers have been planted, and as of October 2020, producers had over 13,500 acres actively enrolled in CREP. Contact your local conservation district or the RCO to learn more.

- [Conservation Reserve Enhancement Program](#) (NRCS)
- [Environmental Quality Incentives Program](#) (NRCS)
- [Conservation Stewardship Program](#) (NRCS)
- [Conservation Reserve Program](#) (NRCS)
- [Regional Conservation Partnership Program](#) (NRCS)
- [Agricultural Conservation Easement Program](#) (NRCS)
- [Agricultural Land Easements](#) (NRCS)
- WWRP [Farmland Preservation Grants](#) (RCO)

Timber landowners have access to a variety of forestry-oriented conservation incentive programs (see list, below) and can also receive technical assistance from DNR's Forest Stewardship Program ([foreststewardship@dnr.wa.gov](mailto:foreststewardship@dnr.wa.gov) / 360-902-1428):

- [Forestry Riparian Easement](#) (DNR)
- [Rivers and Habitat Open Space Program](#) (DNR)
- [Healthy Forests Reserve Program](#) (NRCS)
- [Family Forest Fish Passage Program](#) (DNR)
- [Forest Legacy](#) (USFS)
- WWRP [Forestland Preservation Grant Program](#) (RCO)

#### 4.3.2 *Tax Reduction Incentives*

Landowners can receive a substantial tax reduction by converting land into "open space" status because of the Open Space Taxation Act ([WAC 458-30](#)), enacted in 1970. Lands with riparian areas often qualify for this incentive; see your county assessor and local planning department for details.

#### 4.3.3 *Technical Assistance*

Local governments and individual landowners who want to improve riparian habitat for a suite of species can request land use advice from a variety of sources, including:

- WDFW regional habitat and district wildlife biologists. Go to <http://arcg.is/1SgsHqk> to find the names and direct contact information for your local biologists, or call the regional office in your area:
  - Region 1 – Eastern: 509-892-1001
  - Region 2 – North Central: 509-754-4624
  - Region 3 – South Central: 509-575-2740
  - Region 4 – North Puget Sound: 425-775-1311
  - Region 5 – Southwest: 360-696-6211

- Region 6 – Coastal: 360-249-4628
- Salmon Recovery Lead Entities or Regional Fisheries Enhancement Groups
- Tribal natural resource departments
- Local [Conservation Districts](#)

#### 4.4 SUGGESTED RESTORATION PRACTICES

The following section provides a series of suggested restoration practices promoted by WDFW, other state and federal agencies, and conservation partners. We encourage consideration of these activities and others within and adjacent to the RMZ, as delineated in accordance with our recommendations in Chapter 2. Further, it is not unusual to find other types of Priority Habitats (e.g., wetlands, shrub-steppe) adjacent to riparian areas. In such cases, restoration practices should not degrade or disturb the adjacent habitat, but rather—if feasible—improve it in addition to improving the riparian habitat. The same approach should be used where riparian-adjacent Priority Species areas are present.

Like most restoration practices, the ones recommended below can range in complexity, both biologically and technically, so landowners are strongly encouraged to seek technical assistance from WDFW and other experts before taking any action: This will help save money, time, and greatly increase the likelihood of success for any restoration activity. Landowners should also be aware that many of these activities may require permits<sup>11, 12</sup> issued by one or more agencies such as WDFW for the [Hydraulic Code rules](#), and DNR for the [Forest Practices rules](#); as well as permits from the local jurisdiction.

1. Improve quality of vegetation for both aquatic and terrestrial wildlife by removing invasive species wherever present. Further, to avoid the likely return of invasive species, cleared areas should be replaced with native riparian vegetation: specifically, native vegetation that provides needed ecosystem functions as described in Volume 1 and throughout this document (e.g., shade, large wood, pollution removal).
2. Where riparian areas already possess some native vegetation, enhance them with a greater mixture of native plants that provide necessary habitat components (forage, cover, breeding, roosting, etc.) for a diversity of species and multiple riparian functions (e.g., streambank stability, wood recruitment, organic litter input, and pollutant removal). The specific mix of vegetation will vary by ecoregion and local needs, but likely includes conifers, grasses, and herbaceous plants.
3. Increase off-channel habitat and improve natural flow regimes by removing dikes or levees and restoring access to and within the floodplain.

---

<sup>11</sup> The Governor's ORIA Office provides additional assistance for general permitting questions ([https://www.oria.wa.gov/site/alias\\_oria/347/Permitting.aspx](https://www.oria.wa.gov/site/alias_oria/347/Permitting.aspx))

<sup>12</sup> Larger projects may also trigger permit requirements with federal agencies, such as the U.S. Army Corps of Engineers (USACE).

4. In areas of incised channels, reintroduce beaver or construct beaver dam surrogates to store sediments, raise streambed elevation, raise water table elevation, and restore riparian vegetation.
5. Remove reed canary grass, which can greatly inhibit channel morphology and aquatic species movement. (Management techniques for reed canary grass vary and are often site-specific: contact your local WDFW regional habitat biologist for technical assistance.)
6. Through proper consultation with WDFW and tribal biologists, increase the presence of large wood in streams and rivers to improve habitat for salmon, resident fish species, and aquatic amphibians.
7. Increase connectivity through removal of non-fish passing culverts. If replacement culverts are needed, ensure they are adequately sized and climate-change-resilient; see WDFW's online resource on [Incorporating Climate Change into the Design of Water Crossing Structures](#) (Wilhere et al. 2016).
8. Reduce soil erosion by increasing vegetation complexity and density, excluding (or substantially minimizing) soil compacting activities, and implementing upland soil management techniques where applicable.
9. For agricultural operators: add and/or improve fencing structures to increase the amount of riparian area acreage from which livestock are excluded to reduce compaction, erosion, and overgrazing.

# CHAPTER 5. IMPROVING PROTECTION THROUGH ADAPTIVE MANAGEMENT

## 5.1 INTRODUCTION

Adaptive management is widely recognized as an essential component of effective natural resource management because it provides a systematic process for continually improving policies and management through outcome-based learning. The adaptive management process is a continual cycle of planning, acting, monitoring, evaluating, and adjusting (Figure 5.1). This feedback loop provides information for making adjustments that focus on improving decisions in all phases of resource management. The utility of adaptive management programs should be considered by conservation practitioners, landowners, and land use planners to ensure that conservation actions achieve desired outcomes: in the case of this document, that means preserving, protecting, and restoring healthy, intact, and fully functioning riparian areas. In addition to improving ecosystem outcomes, adaptive management should improve clarity of regulations—resulting in increased transparency to all stakeholders.

All cities and counties are currently protecting critical areas, including riparian ecosystems, through a variety of regulatory and non-regulatory mechanisms. One regulatory challenge is understanding how well these mechanisms meet their intent of protecting ecosystem functions and values and how to make improvements where they are falling short. This chapter was written in collaboration with the Washington Department of Commerce (Commerce) and relies heavily on the Commerce’s 2018 update of the [Critical Areas Ordinance Handbook](#) (Bonlender 2018), with one exception, as noted.

**Figure 5.1.** A simple depiction of the adaptive management cycle (modified from Bormann et al. 1994).

The process for monitoring we describe here supports both local and larger-scale actions that improve our collective efforts to protect riparian ecosystems throughout the state. For example, the Puget Sound Partnership (Partnership) uses “[Vital Signs](#)” of ecosystem health and recovery, such as riparian forest cover, to understand ecosystem condition, articulate shared goals and progress, and inspire action towards meeting those goals.

Adopting an adaptive management program can allow local governments to respond more quickly and meaningfully as new information become available. A willingness to address issues identified through this process is critical to the idea of adaptive management.

## 5.2 COMMON QUESTIONS ADDRESSED BY ADAPTIVE MANAGEMENT

Adaptive management does not have to be expensive or complicated to be useful. We believe local jurisdictions can maximize their investment in adaptive management by focusing on two types of monitoring related to their own regulatory process (explained in more detail in the next section).

We begin by discussing three basic types of monitoring because we have found it instructive to understand how different monitoring types can be hierarchically or sequentially staged, based on the types of questions they seek to answer: implementation monitoring, effectiveness monitoring<sup>13</sup>, and validation monitoring.

### 5.2.1 *Implementation Monitoring*

*Implementation monitoring* typically helps the permit issuer (permitter) answer the following questions about its permitting system, by looking at the outcomes of individual permits:

- Are permits consistent with regulations?
- Do permits contain all necessary conditions or provisions for a project?
- Does the permitter issue consistent permits (same requirements) for all permittees?

Implementation monitoring can also include:

- Permit *compliance monitoring*, which asks if the permittee followed or complied with each permit condition or provision and refrained from conducting unpermitted activities. Compliance monitoring usually takes place very soon after completion of permitted work.
- Keeping track of unpermitted activities; that is, finding changes in land use or management that require a permit but where no permit of any kind was issued.

---

Monitoring does not have to be complicated. Even if a city or county chooses to do only permit implementation monitoring, this will provide key information that can improve the permit process, and an individual landowner can check whether choices like enhancing native plantings produce the desired results.

---

### 5.2.2 *Effectiveness Monitoring*

In Commerce's 2018 Critical Areas Handbook, *effectiveness monitoring* is a form of long-term implementation monitoring. In other words, effectiveness monitoring looks at permit compliance as a while to determine whether permit conditions/provisions (e.g., buffer widths) are followed over time.

For the purposes of this document, we describe effectiveness monitoring a bit differently: Specifically, effectiveness monitoring is a way to determine whether permit conditions/provisions

---

<sup>13</sup> As explained further in Section 5.2.2, we describe and use the term effectiveness monitoring somewhat differently than how it is described in Commerce's 2018 Critical Areas Handbook.

are working relative to intended environmental outcomes. For example, “Are permit conditions/provisions leading to the riparian function(s) (e.g., shade, bank stability) that they were intended to provide?” Effectiveness monitoring typically involves some on-the-ground measurement of environmental variables affected by land use activities.

### 5.2.3 Validation Monitoring

Research within the adaptive management framework is often referred to as *validation monitoring*. In the context of land use regulations, the questions relate to how management of critical areas (e.g., riparian) affects the specific environmental resource it was intended to protect (e.g., water quality, salmon). Validation monitoring may be beyond the fiscal means of most local governments. Moreover, it often involves questions that must be addressed over large spatial extents (e.g., at watershed or multi-watershed scale). In comparison, implementation and effectiveness monitoring are often tied to local jurisdiction’s regulatory processes at the site scale: For these reasons, the next two sections focus more on these two types of monitoring

## 5.3 RECOMMENDED IMPLEMENTATION MONITORING EFFORTS

We advise local governments to focus first on using implementation monitoring to evaluate their regulatory processes that affect riparian ecosystems. Implementation monitoring tracks execution of the permitting system from the perspective of both the permit issuer (permittor) and permit holder (permittee) (Figure 5.2). This effort can result in regular status reports that help demonstrate how well local governments and permittees are working together to meet resource objectives in a fair and consistent manner.

**Figure 5.2.** Depiction of the adaptive management cycle specific to permit compliance.

Implementation monitoring provides key information for permitting process improvement (**Error! Reference source not found.**2; Table 5.1). Even in situations where local governments cannot monitor all steps in their permitting process, monitoring any step—regulations to permit conditions/provisions, permit provisions to construction, construction to inspections, or inspections to enforcement—can provide valuable feedback about the quality of regulatory processes.

**Table 5.1.** Key questions for implementation monitoring during the Critical Areas permit review process.

| Process Steps       | Key study questions to evaluate permit implementation                                                                                                                                                                                                                                                                                                          | Proposed metrics                                                                                                                                                                                     |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Application         | Was adequate information gathered from the permit applicant?<br>Did the local government provide timely and necessary technical assistance to the permit applicant?                                                                                                                                                                                            | Number and percent of complete applications. i.e., include all information necessary to issue a permit.<br>Number and percent by type of permit applications missing information                     |
| Permit              | Do permit provisions follow the local government code?                                                                                                                                                                                                                                                                                                         | Number and percent of permit provisions by type consistent with code.                                                                                                                                |
| Permit              | Do permit provision identify intent of protection and how it can be accomplished? (e.g., area of tree retention, distance of structure from stream, clearing, grading, or storm water provisions, replanting requirements, extent of impervious surface.)                                                                                                      | Number and percent of (complete) permits (i.e., include all provisions that enable a permittee to be fully compliant with the permit.)<br>Number, percent, and type of missing provision/information |
| Permit (variance)   | If a variance was granted, is the reason for the variance clearly stated?                                                                                                                                                                                                                                                                                      | Percent of variances by type justified by code or policy<br>Percent of permits with variances by type.                                                                                               |
| Permit (mitigation) | If compensatory mitigation was required, were the unavoidable impacts clearly identified/quantified?<br>Was the rationale clearly stated?                                                                                                                                                                                                                      | Number and percent of permits by type with unavoidable impacts<br>Percent of permits by type with quantified mitigation requirements                                                                 |
| Compliance          | Post-Construction Visit: Did the permittee comply with the permit? (Requires field measurements of some or all the provisions in the permit. For riparian ecosystems, key provisions to inspect include RMZ width, retention of trees, replanting, structure distances from stream, area of impervious surface, and implementation of storm water provisions.) | Number and percent by type of provision that were out of compliance.                                                                                                                                 |
| Enforcement         | Are enforcement actions necessary to meet permit provisions and/or the regulations?                                                                                                                                                                                                                                                                            | Number and percent by type of permit enforcement actions.                                                                                                                                            |

Because little or no fieldwork is required, the easiest and least expensive step to monitor is the link between regulations and permit provisions: that is, whether local land use regulations have been translated into permit provisions that can be understood easily by permittees. We recommend that some implementation monitoring become part of all local regulatory programs, even if it only on a relatively small subset of permits selected at random. A database for storing information on each

step (i.e., a permit tracking system—see Table 5.1, Figure 5.3) is a critical tool for creating a complete system of accountability.

**Figure 5.3.** One system of permit accountability that includes implementation monitoring of internal permit processes, inspection for permit compliance, a database from which to judge outcomes, and a feedback loop connecting outcomes with policy intent.

Long-term implementation monitoring can help answer additional questions, such as: “Are rules/regulations intended to provide long-term protection of critical areas (e.g., RMZs) actually followed or maintained over time?” One way to answer this is by looking at changes in land cover, which describes the type and amount of vegetation, roads, and buildings occurring on the landscape. By comparing high quality aerial photographs taken of the same locations over time, change can be quantified and attributed to specific activities, both from natural disturbances (e.g., wildfires, river channel migration) and human activities (e.g., timber harvesting, residential subdivision construction, highway widening). In Section 5.5, we describe one such process WDFW developed and for which information for many parts of the state are already available.

## 5.4 EFFECTIVENESS OF REGULATORY PROTECTIONS OF CRITICAL AREAS

Where implementation monitoring has been successful, that is, either documenting a highly functional permitting process or improving poorly performing permitting process, we encourage additional effort on effectiveness monitoring. As described above, our primary goal for effectiveness monitoring would focus on understanding how well the permit conditions/provisions lead to measurable outcomes on the ground (e.g., protection/restoration of one or more riparian functions or values) over an extended period.

## 5.5 USING LAND COVER CHANGE TO UNDERSTAND LONG-TERM REGULATORY PROTECTION

High Resolution Change Detection ([HRCD](#)) is a tool that is useful for detecting changes in two specific types of land cover (tree canopy and impervious surfaces) over set time periods. Land cover change analysis like HRCD can show jurisdictions the degree to which critical area regulations are maintaining RMZs as intended. This information can then help shape if, where, why, and how adjustments to permitting processes should occur. By combining land cover change analysis with targeted questions about permitting processes, jurisdictions can begin to adaptively manage changes to their overall regulatory system.

---

## Adaptive Management Framework in the Voluntary Stewardship Program

The Voluntary Stewardship Program (VSP) was authorized by the Legislature in 2011 through RCW 36.70A.705. The goals of VSP are to protect and enhance critical areas where agricultural activities are conducted, maintain and improve the long-term viability of agriculture in the State of Washington, and reduce conversion of farmland to other uses. The program provides counties with an alternative approach from traditional development regulations that require protection (and encourage enhancement) of critical areas at the individual parcel scale. Instead, VSP relies upon voluntary practices and incentive programs to protect (and enhance) at a watershed scale. Counties “opted-in” to VSP, and as of 2019, 27 of the state’s 39 counties are participating.

Under VSP, local workgroups created work plans that include benchmarks for protection and enhancement of critical areas designed to be achieved through voluntary and incentive-based actions. VSP requires monitoring and adaptive management to maintain and enhance critical areas, including riparian ecosystems, and directs workgroups to monitor at the watershed or sub-watershed scale. Key requirements for county-level programs include:

1. Establishing a durable system to track and report goals, benchmarks, and performance metrics.
2. Developing implementation and effectiveness monitoring programs and conducting monitoring on a pre-determined schedule.
3. Establishing an adaptive management program with (a) “triggers”; (b) subsequent actions to take; and (c) a process to review/update both the triggers and actions over time.
4. Reporting on the achievement of protection and enhancement goals and benchmarks at specified intervals.

Numerous counties have utilized WDFW’s recommended VSP Adaptive Management Matrix in approved VSP Work Plans. Examples include:

- Chelan County, Appendix I (Approved April 2017)
- Grant County, Tables 5-7 through 5-10 (Approved June 2017)
- Asotin County, Tables 5-3 through 5-5 (Approved May 2018)
- Okanogan County, Chapter 6 (Approved September 2018)
- Spokane County, Section 4 (Approved November 2018)

Jurisdictions can adapt matrices as templates for connecting goals, benchmarks, performance metrics, monitoring, and adaptive management for other uses beyond VSP. These matrices can be modified as frameworks to identify specific elements of any adaptive management plan.

---

The example in the following section is adapted from Commerce’s Critical Areas Handbook (Bonlender 2018). Chapter 7 of that document provides a number of similar monitoring program examples, nearly all of which were developed by cities or counties.

### 5.5.1 *Example: WDFW/Thurston County Shoreline Master Program*

In 2015, Thurston County and WDFW utilized a National Estuary Program grant to quantify shoreline vegetation, land cover change, and evaluate land use permit compliance. Specifically, Thurston County used WDFW’s HRCD data to monitor compliance within the County’s Shoreline Master Program (SMP) jurisdiction. This project developed a [protocol manual](#) for using HRCD for this purpose, available to all jurisdictions within the Puget Sound region.

One goal of the pilot project was to answer several related sets of questions:

For Thurston County:

- What land cover change is happening within designated SMP areas? What change is happening throughout the Deschutes River watershed (WRIA 13)?
- How does change known by permit records compare with detected changes by HRCD?
- What changes, if any, can be made to the land use permits or permitting process that could increase the relevancy or efficacy in utilizing the HRCD in compliance monitoring?

For WDFW:

- How well can HRCD detect changes relative to land use permit records?
- Using Thurston County's SMP area as an example test area, what land cover changes are happening which HRCD is not capturing?
- With the development of a HRCD user manual, can HRCD be successfully utilized by other entities in the absence of direct assistance by WDFW?

The pilot quantified increases in impervious surfaces and decrease in tree canopy within marine areas of the SMP jurisdiction and checked for relevant permits issued. It consisted of five phases:

*Phase 1: Initial SMP Change Analysis:* Staff from WDFW's Habitat Program and the County's Long-Range Planning Department intersected the HRCD dataset with the County's SMP area and tax parcel data within ArcGIS for three time periods of HRCD availability (2006 to 2009, 2009 to 2011, and 2011 to 2013). Staff compared known areas of change to those locations with the county's land use permit records to find locations of observed change via HRCD without any permit record. During this phase, land cover change statistics were also produced, including total area of change and discrete occurrences of land cover change events.

*Phase 2: Learning What the HRCD Misses:* Using the SMP area in the County, WDFW staff manually looked for land cover changes not captured by the HRCD analysis, to understand how accurate HRCD was in capturing all land cover change situations (rates of omission error).

*Phase 3: Developing a Standardized Method for Utilizing the HRCD:* A major goal of this project was to develop support materials for others to be able to utilize HRCD to answer land use management questions independent of WDFW staff assistance. Using lessons learned in Phases 1 and 2, WDFW and the County agreed upon a recommended method for applying HRCD to a specific management question, and collaboratively developed a "how-to" manual. In this phase, WDFW staff also developed a web-based service (<https://hrcd-wdfw.hub.arcgis.com>) where users can download the HRCD dataset, detail the methodology of HRCD construction, find WDFW contact information, and more.

*Phase 4: Testing the Manual through Remaining SMP Analysis in WRIA 13:* Using only the HRCD dataset and the manual produced in Phase 3, County staff examined land cover change within the remaining SMP areas within WRIA 13 successfully for the same three time periods that HRCD data was available and utilized in the earlier phase.

*Phase 5: Training and Outreach:* With the lessons learned and products derived from Phases 1 through 4 of the project, staff worked in conjunction with the [Coastal Training Program](#), managed by Ecology, to develop and deliver a workshop for planning staff within other state agencies, local

governments, and some non-governmental organizations. WDFW also used this opportunity to train internal staff on the benefits, limitations, and uses of HRCD.

The evaluators analyzed land cover change within Thurston County's SMP area between 2006 and 2013, pulling permit records from timeframes that corresponded with the available HRCD datasets. The project's findings were very helpful, not only because of the information collected, but also in providing proof of concept for several of the steps/tools.

For example: The utility of HRCD in analyzing patterns of land cover change in a specific geographic area of concern were well demonstrated. The HRCD analysis found that, from 2006 to 2013, less than half of one percent (0.39%) of the riparian area contained within the SMP had land cover change – approximately two-thirds of this was due to canopy loss, with one-third due to new impervious surfaces. The HRCD analysis did not find any permitted developments that were out of compliance, though it did find unpermitted events (e.g., tree removal) in each time period studied.

Furthermore, the HRCD dataset proved to be relatively simple to use. With the development of standard application methods, Thurston County was able to complete an analysis of their remaining SMP area without any further assistance from WDFW.

On the flip side, Thurston County found that comparing actual permit compliance with HRCD data was “tedious and difficult” because of limitations with the county's permit tracking database ([AMANDA](#)). For example, in many cases, land use permits did not include enough information to determine conclusively that a parcel with observed change via HRCD was out of compliance or determine that the parcel had a permit record during the study's timeframe in question.

Local governments can use HRCD analysis at the start to find land cover changes that are otherwise unknown; as they begin to understand patterns, HRCD analysis provides indications to identify locations that warrant closer investigation through other methods.

## 5.6 CONCLUSION

Implementation and effectiveness monitoring are important parts of adaptive management and can be undertaken relatively easily by local governments. Many of our riparian ecosystems are already degraded and stressed, so it is worth our while to investigate whether the actions put in place to protect them are being carried out as required and leading to the specific environmental responses that were intended. This is now more important than ever, because in spite of advances in science and efforts to improve regulatory processes, climate change and population pressures are increasingly confronting many parts of the state. Using monitoring and adaptive management to track successes and failures and then learning from both will make our challenges easier to overcome.

## GLOSSARY OF TERMS

**Active channel:** The active channel is defined by the lower limit of continuous riparian vegetation (Naiman et al. 1998) and may be delineated by absence of both moss on rocks and rooted vegetation (USFS 2008). The upper most elevation of the active channel is sometimes equated with the ordinary high-water mark.

**Active floodplain:** Located between the active channel and adjacent terrace or hillslopes (Fetherston et al. 1995; Harris 1987). Depending on the watershed, the flood return interval of the active floodplain varies between 1 and 10 years (Wolman and Leopold 1957; Ward and Stanford 1995; Lichvar et al. 2006; Williams et al. 2009; BLM 2015).

**Adaptive management:** The systematic acquisition and application of reliable information to improve management over time. It often includes treating management decisions as experiments in order to address critical uncertainties and learn more quickly from experience. It involves setting objectives, monitoring conditions, and adjusting management based on results. Hallmarks of a sound adaptive management program include: (1) adequate funding for monitoring and research, (2) a willingness to change course when pre-established triggers are reached, and (3) a commitment to gather data and evaluate conditions at appropriate spatial extents and time scales. *See Ecosystem-based management and WAC 365-195-920(2).*

**Anadromous fisheries:** The commercial, recreational or subsistence harvest of fish that are born in freshwater, rear at sea, and return to freshwater to spawn. Anadromous fisheries of Washington include salmon (Chinook, coho, chum, sockeye, and pink), steelhead, bull trout, coastal cutthroat trout, green sturgeon, white sturgeon, eulachon, longfin smelt, and Pacific lamprey.

**Aquatic species:** Wildlife species that live in marine or freshwater including fish, shellfish (e.g., clams, snails, mussels), amphibians (e.g., frogs, salamanders), reptiles (e.g., turtles), crustaceans (e.g., crayfish), insects (e.g., larval mayflies, stoneflies, caddisflies, dragonflies) and various other invertebrates.

**Best Available Science:** Information produced through a valid scientific process that WDFW or another local, state or federal agency has determined represents the best available science consistent with criteria set out in WAC 365-195-900 through 365-195-925. (Volume 1 of this document is an example of Best Available Science regarding riparian ecosystems.)

**Biota:** The animal and plant life of a region, habitat, or geological period.

**Buffer:** The area around a critical area that separates the critical area from incompatible uses. For example, a 200m buffer may be established around a heron-nesting colony (the critical area) to keep suburban land uses from disrupting the colony. *See WAC 365-190-130(3)(a).* Riparian ecosystems are both buffers (for instream habitat) and critical areas on their own merit.

**Channel Migration Zone:** The area within which a river channel is likely to migrate and occupy over a specified time period (e.g., 100 years).

**Channel slope or gradient:** The average steepness of a stream segment measured as its change in elevation divided by its length. Typically, a segment's gradient is considered low if less than 2%, moderate between 2% and 4%, and high if greater than 4%.

**Classification** (critical area): Defining categories to which critical areas are assigned. The Priority Habitats and Species (PHS) program provides WDFW's recommended classification scheme for Fish and Wildlife Habitat Conservation Areas. Classification precedes designation in counties' and cities' effort to protect critical areas. *See* WAC 365-190-040(4).

**Complexity:** The complicated state seen in dynamic environments that contain multiple components and processes that interact with one another in a web of interactions whose outcomes are often unpredictable. Complexity can be described with conceptual models; outcomes of well-understood complex phenomena can be partially predicted using computer models.

**Connectivity:** Landscape connectivity is the physical relationship between landscape elements. Functional connectivity describes the degree to which landscapes facilitate or impede the movement of organisms between areas of habitat.

**Critical Aquifer Recharge Area:** Areas with an essential recharging effect on aquifers used for potable water. One of five types of Critical Areas identified in the Growth Management Act.

**Critical Area(s):** Places that the Growth Management Act requires all counties and cities to designate and protect, specifically, (1) Wetlands; (2) Critical Aquifer Recharge Areas; (3) Fish and Wildlife Habitat Conservation Areas (e.g., Riparian Management Zones); (4) Frequently Flooded Areas; and (5) Geologically Hazardous Areas. In developing policies and regulations to protect the functions and values of critical areas, counties and cities are required to include best available science and give special consideration to conservation or protection measures necessary to preserve or enhance anadromous fisheries. *See* RCW 36.70A.172(1). The presence of a critical area may limit some land development options. *See* WAC 365-190-040(6).

**Delineation** (critical area): The act of applying definitions or performance standards in the field to identify the boundary of a critical area.

**Designation** (critical area): Assigning critical areas into established categories and specifying their general distribution, location, and extent. Designation can be made by maps (which are useful for public awareness and for identifying if a proposal may affect a critical area) and by performance standards or definitions (which allow for specific identification and site-scale delineation during permit review). WDFW's Priority Habitats and Species (PHS) program provides the agency's recommended designation maps and performance standards/definitions for Fish and Wildlife Habitat Conservation Areas. Designation occurs after classification in counties' and cities' efforts to protect critical areas. *See* WAC 365-190-040(5).

**Disturbance regime:** The frequency, magnitude, and duration of disturbance events.

**Disturbance:** A pronounced, temporary change in environmental conditions within an ecosystem. Disturbances often act quickly and can alter ecosystem composition, structure, and function.

**Ecological (biological) integrity:** Ability of an ecological system to support and maintain a community of organism that has species composition, diversity, and functional organization comparable to those of natural habitats within a region. An ecological system has integrity when its dominant ecological characteristics (composition, structure, function, and processes) occur within their historical ranges of natural variability. *See* Historical condition and Range of natural variability.

**Ecosystem(s):** A spatially explicit unit of the Earth that includes all the organisms, along with all components of the abiotic (chemical and physical) environment. Ecosystems have composition, structure, and functions.

**Ecosystem composition** (or ecological composition): All living (biotic) and nonliving parts of an ecosystem.

**Ecosystem function(ing)** (or ecological function): (1) The process or cause and effect relationship underlying two or more interacting components, e.g., terrestrial plant material as food/substrate for aquatic invertebrates. (2) The sum of processes that sustain the system. (3) The capacity of natural processes and components to provide goods and services that satisfy human needs, either directly or indirectly. Ecosystem functions can be conceived as a subset of ecological processes (*See Ecosystem process*).

**Ecosystem process** (or ecological process): Interactions among components of an ecosystem, biotic (living organisms) and abiotic (chemical and physical) components. Many processes involve transfer, conversion, or storage of matter or energy (*See Ecosystem function*).

**Ecosystem structure** (or ecological structure): The arrangement of and relations among the parts or elements (components) of an ecosystem.

**Ecosystem-based management (EBM):** Management driven by explicit goals; executed by policies, protocols, and practices; and made adaptable by monitoring and research; based on our best understanding of the ecological interactions and processes necessary to sustain ecosystem composition, structure, and function. EBM acknowledges that humans are an important ecosystem component and focuses on managing human activities within ecosystems. EBM often involves balancing ecological, economic, and social objectives within the context of existing laws and policies.

**Enhance:** To improve a critical area's existing ecosystem processes, structure, and/or functions so that its ecological integrity is more like its historical condition.

**Erosion:** The loosening and transport of soil particles and other sediment by water. Terrestrial erosion includes raindrop splash erosion, overland flow sheet erosion, surface flow rill (shallow) and gully (deeper) erosion. Channel erosion includes streambank erosion and channel incision (gouging). Rill and gully erosion diminish the ability of the riparian area to trap sediment and pollutants and can often be avoided with intact riparian vegetation.

**Fish and Wildlife Habitat Conservation Areas (FWHCA):** A type of Critical Area specified in the Growth Management Act. The intent of FWHCAs are to maintain populations of species in suitable habitats within their natural geographic distribution so that (1) the habitat available is sufficient to support viable populations over the long term, and (2) isolated subpopulations are not created. FWHCAs come in a variety of types including waters of the state, places with which listed species have a primary association, habitats and species of local importance, and riparian ecosystems. *See WAC 365-190-130.*

**Flow regime** (stream): The distribution of stream flow through space and time. Flow regimes can be described by their magnitude (e.g., mean annual, hourly maximum), timing, frequency or return periodicity, duration, spatial distribution, and rate of change. The pathways that water takes to reach a stream (e.g., surface runoff) and within a stream exert a strong influence on the flow regime.

**Function:** Physical, chemical, or biological processes that occur within an ecosystem. WAC 365-196-830 says, “Functions are the conditions and processes that support the ecosystem. Conditions and processes operate on varying geographic scales ranging from site-specific to watershed and even regional scales.” See also Ecosystem function(ing) and Ecosystem process.

**Habitat:** The resources and conditions presented in an area that support the functional needs of a species (e.g., hiding, migration, resting, feeding, breeding, and rearing), and which are necessary for its survival and reproduction. Habitat is species-specific, scale dependent, and more than vegetation composition or structure.

**Hazard Tree:** A tree that a jurisdiction’s building official or other recognized professional (e.g., certified arborist, registered landscape architect, or certified forester) has determined poses a near-term hazard to public safety or to an existing permanent structure or public utility.

**Herbaceous:** Non-woody plants such as grasses and ferns.

**Historical condition:** See Ecological integrity and Range of natural variability.

**Hydrology:** Description of the properties, distribution, movement, and storage of water on and below the Earth’s surface.

**Impervious surface:** Ground surfaces that resist or prevent water infiltration, e.g., roofs of houses, roadways.

**Imputed:** estimated; a value assigned to missing data by inference from the values of data within the same dataset.

**Infiltration:** The rate or process by which water on the ground enters the soil.

**Instream:** Within flowing freshwater; also, the area waterward of the Ordinary High-Water Mark.

**Large Woody Debris:** Large dead woody material (such as fallen trees and branches) in various stages of decomposition that provide nutrient capital to forest and aquatic resources and serve as habitat in forest and riparian ecosystems. Large wood is usually defined as having diameter greater than 4 in (10 cm) and length greater than 6 ft ( $\approx 2$  m).

**Low Impact Development (LID):** A storm water and land-use management strategy that tries to mimic natural hydrologic conditions by emphasizing pre-disturbance hydrologic processes of infiltration, filtration, storage, evaporation, and transpiration.

**Mitigation:** General category of measures that a proponent may take to avoid, minimize, and compensate for impacts.

**Mitigation sequence:** The stepwise process of protecting a critical area through, first (1) avoiding harm to the critical area to the maximum extent practicable, then (2) minimizing unavoidable harm to the maximum extent practicable, and finally (3) providing compensation for all unavoidable harm by restoring, creating, enhancing, or preserving the critical area’s ecological functions and values to replace those impacted or lost through permitted activities.

**Monitoring:** The process of observing and checking the progress or quality environmental conditions for the purposes of adaptive management. Often described as having three types – implementation, effectiveness, and validation.

**Morphology** (stream channel, aka fluvial geomorphology): A stream channel's shape and how it changes over time. Channel morphology is influenced by the abundance and variation in sediment sources, the ability of water to transport sediment downstream, and interactions of sediment with riparian vegetation and woody debris.

**Off-Channel Habitat:** Overflow channels, sloughs, alcoves, wetlands, and small streams found within the floodplains of larger river channels. Off-channel habitat consists of waters connected to and draining into rivers and streams by inundation during peak flow events (Smith 2005; WAC 222-16-031). Off-channel habitat provides habitat for salmonids and other aquatic species which often afford (1) spawning habitat that does not experience scouring high flows; and (2) summer rearing habitat that does not experience loss of stream flow.

**Ordinary High Water Mark (OHWM):** (1) That mark that will be found by examining the bed and banks and ascertaining where the presence and action of waters are so common and usual, and so long continued in all ordinary years, as to mark upon the soil a character distinct from that of the abutting upland (Washington Department of Ecology 2016). (2) That line on the shore established by the fluctuations of water and indicated by physical characteristics such as a clear, natural line impressed on the bank, shelving, changes in the character of soil, destruction of terrestrial vegetation, the presence of litter and debris, or other appropriate means that consider the characteristics of the surrounding areas (U.S. Army Corps of Engineers, 2014).

**Organic litter:** Plant, leaf, tree, or soil litter, and duff are dead plant materials that have fallen to the ground. In this document, organic litter is referenced as available for contributions to the stream system.

**Passive Restoration:** Allowing natural succession to occur in an ecosystem after removing a source of disturbance.

**Population viability** (local): The likelihood that a population of a species will persist for some length of time.

**Precautionary principle:** Erring on the side of not harming resources when faced with uncertainty, especially for potential harm that is essentially irreversible. Utilizing a precautionary approach in land use planning involves: (1) taking preventive action (avoiding impacts); (2) shifting the burden of proof to the project proponents; (3) exploring a wide range of potential alternatives; and/or (4) including multiple stakeholders and disciplines in decision making.

**Priority Area:** The area within a Priority Species' natural geographic distribution within which protective measures and/or management actions are needed to (1) support viable populations over the long term and (2) avoid creating isolated subpopulations.

**Priority Habitat:** A State of Washington habitat type with unique or significant value to many species; an area with one or more of the following attributes: (1) comparatively high fish and wildlife density; (2) comparatively high species diversity; (3) important breeding habitat; (4) important seasonal ranges; (5) important movement corridors; (6) limited availability; (7) high vulnerability to habitat alteration; or (8) unique or dependent species. Examples of Priority Habitats include but are not limited to instream, riparian, shrub steppe, Oregon white oak woodlands, freshwater wetlands, and marine nearshore.

**Priority Habitats & Species (PHS):** WDFW's primary means of transferring fish and wildlife information from resource experts to local governments, landowners, and others for the protection of fish, wildlife, and habitat. Includes endangered, threatened, sensitive, candidate, and vulnerable species and habitats deemed priorities of WDFW and reflective of best available science. *See* WAC 365-190-130.

**Priority Species:** A State of Washington fish or wildlife species requiring protective measures and/or management actions to ensure its survival. A Priority Species fits one or more of the following criteria: (1) is a state-listed endangered, threatened, sensitive, or candidate species, (2) has vulnerable aggregations, or (3) is of recreational, commercial, and/or tribal importance. Examples of Priority Species include but are not limited to steelhead/rainbow trout, bull trout/Dolly Varden, great blue heron, cavity-nesting ducks, sage grouse, fisher, orca, and elk.

**Process:** *See* Ecosystem process.

**Protect:** To prevent the degradation of existing ecosystem functions and values.

**Range of natural variability** (or Historical range of natural variability): Refers to the range of ecological conditions (components, structures and functions) in a time period before widespread anthropogenic changes.

**Recruitment** (wood): The process of wood moving from a riparian area to the stream channel. Sources of recruitment include bank erosion, windthrow, landslides, debris flows, snow avalanches, and tree mortality due to, for example, fire, ice storms, beavers, insects, or disease. Dominant factors include, but are not limited to, channel width, slope steepness, slope stability, forest composition and structure, and local wind patterns.

**Refugia** (singular Refugium): sites to which biota retreat, persist in and potentially expand from under changing environmental conditions (Keppel et al. 2012).

**Riparian:** An adjective meaning alongside a waterbody: stream, river, lake, pond, bay, sea, and ocean. Riparian areas are sometimes referred to by different names: riparian ecosystems, riparian habitats, riparian corridors, or riparian zones. Depending on the contexts, these terms may have somewhat different meanings.

**Riparian area:** A defined area encompassing both sides of a water body, composed of aquatic ecosystems (i.e., the river or stream), riparian ecosystem, and riverine wetlands. Riparian areas are three dimensional: longitudinal up and down streams, lateral to the width of the riparian ecosystem, and vertical from below the water table to above the canopy of mature site-potential trees (NRC 2002).

**Riparian buffer:** Buffer refers to its purpose, which is to reduce or prevent adverse impacts to water quality, fisheries, and aquatic biodiversity from human activities occurring upslope of the buffer. Riparian buffers managed specifically for pollutant removal may also be called a vegetated filter strip.

**Riparian ecosystem:** Riparian areas are transitional between terrestrial and aquatic ecosystems and distinguished by gradients in biophysical conditions, ecological processes, and biota. They are areas through which surface and subsurface hydrology connect waterbodies with their adjacent uplands. They include those portions of the ecosystem distinguished by gradients (i.e., riparian

zones) and portions of terrestrial ecosystems that significantly influence exchanges of energy and matter with aquatic ecosystems (i.e., the Zone of Influence). Our definition of riparian ecosystem does not include adjacent waters (i.e., rivers or streams, but does include riverine wetlands) and recognizes the riparian zone as a distinctive area within riparian ecosystems.

**Riparian Management Zone:** A delineable area defined in a land use regulation; often synonymous with riparian buffer. For the purposes of this document, we define the RMZ as the area that has the potential to provide full riparian functions. In many forested regions of the state this area occurs within one 200-year site-potential tree height measured from the edge of the stream channel. In situations where a CMZ is present, this occurs within one site-potential tree height measured from the edges of the CMZ. In non-forest zones the RMZ is defined by the greater of the outermost point of the riparian vegetative community or the pollution removal function, at 100-feet.

**Riparian values:** The benefits that riparian ecosystems provide to society, including but not limited to flood damage reduction, water quality improvement, provision of harvestable populations of salmon, and provision of recreational opportunities. Riparian values have direct economic consequences to local communities through fishing opportunities, and flood and water quality protection, among others.

**Riparian zone:** A distinctive area within riparian ecosystems. The riparian zone contains wet or moist soils and plants adapted to growing conditions associated with periodically saturated soils. *See* Riparian ecosystem.

**Risk:** A situation involving exposure to danger, harm, or loss. Risk reflects the magnitude of the adverse impact and its probability of occurring. Risk is appropriately managed by applying the precautionary principle (especially for irreversible losses) and through adaptive management.

**Salmonid:** A family of fish comprised of salmon, trout and whitefish. Native salmonid species in Washington State include: Chinook Salmon (*Oncorhynchus tshawytscha*), Chum Salmon (*O. keta*), Coho Salmon (*O. kisutch*), Pink Salmon (*O. gorbuscha*), Sockeye Salmon/Kokanee (*O. nerka*), Steelhead/Rainbow Trout (*O. mykiss*), Cutthroat Trout (*O. clarki*), Bull Trout (*Salvelinus confluentus*), Dolly Varden (*S. malma*), Pygmy Whitefish (*Prosopium coulteri*), and Mountain Whitefish (*P. williamsoni*). This list does not include names of subspecies. (*See* anadromous fisheries).

**Site class:** The classification of a site based on the productivity of its dominant tree species. Site classes vary based on local differences in soil nutrients and moisture, light and temperature regimes, and topography. Site classes are typically described as most productive (I) through least productive (V).

**Site-Potential Tree Height:** The average maximum height of the tallest dominant trees for a given age and site class.

**Stronghold:** Habitat strongholds are refugia watersheds that contain high quality habitat with depressed or weak populations. The habitat in these areas has a high to very high potential to support these species. The population level in these areas is not considered to be a function of habitat, but other factors (USFS2001).

**Structure:** *See* Ecosystem structure.

**Succession:** Ecological succession is the process by which the biological community composition recovers over time following a disturbance event.

**Uncertainty** (scientific): The absence of information about the state of something or a relevant variable. Sources of uncertainty include, but are not limited to natural variation (i.e., because outcomes vary in difficult-to-predict ways through time and space), model uncertainty (i.e., we do not understand how things interact with each other), systematic error (e.g., poorly designed experiments or calibrated instruments), or measurement error. *See Risk.*

**Values:** The level of benefits that the space, water, minerals, biota, and all other factors that make up a natural ecosystem provide to support native life forms, including humans (Cordell et al. 2005).

**Vegetative filter strips:** A riparian buffer designed to capture nutrients, contaminant compounds, and sediment transported by run-off. Filter strips are sometimes synonymous with riparian buffers.

**Water quality:** Physical, chemical, and biological characteristics of water that describe its suitability to meet human needs or habitat requirements for fish and wildlife.

**Watershed processes:** The fluxes of energy (e.g., sunlight, wildfire) and materials (particularly water and sediment) that interact with biota (e.g., vegetative cover, salmon, beavers, soil microbes) to form a watershed's physical features and characteristics, which give rise to its instream physical and ecological conditions. These processes occur within a context that reflects the watershed's climate, geology, topography, and existing human land use. *See Ecosystem process.*

**Watershed:** A land area that drains to a common waterbody.

**Wetland:** Those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support—and that under normal circumstances do support—a prevalence of vegetation typically adapted for life in saturated soil conditions. Examples include but are not limited to swamps, marshes, and bogs.

**Zone of Influence:** The portions of terrestrial ecosystems that significantly influence exchanges of energy (e.g., sunlight) and matter (e.g., large wood, sediment, nutrients) with aquatic ecosystems.

## APPENDIX. SITE-POTENTIAL TREE HEIGHT MAPPING TOOL

The Site-Potential Tree Height (SPTH) Mapping Tool helps users find information they need to conserve, protect, and restore riparian ecosystems within a project site. The SPTH mapping tool works on personal computers (PCs) and mobile devices (tablets and smartphones).

### SITE-POTENTIAL TREE HEIGHT MAP DATA

The SPTH mapping tool contains several GIS data layers, explained below:

1. Site-potential Tree Height at 200 Years (SPTH<sub>200</sub>),
2. Imputed<sup>14</sup> SPTH<sub>200</sub> Values for Urban areas,
3. Dryland Ecosystems – No SPTH Values, and
4. Other Lands – No SPTH Values.

#### *Site-potential Tree Height at 200 Years (SPTH<sub>200</sub>)*

WDFW derived the SPTH<sub>200</sub> values from forest productivity site index information using Natural Resource Conservation Service (NRCS) soil polygons and its Soil Data Viewer tool for ArcGIS. The NRCS-provided forest productivity site index values, in feet, were for ages 50 years in Western Washington and typically 100 years in Eastern Washington. WDFW determined SPTH<sub>200</sub> values using tree site index equations. Each soil polygon has one or more tree species records with associated SPTH<sub>200</sub>. When multiple tree species records with associated SPTH<sub>200</sub> are available, WDFW recommends using the largest SPTH<sub>200</sub> value of the tree species historically present at the site (such trees may currently be found on the site, but also may not). For example, if a project site contains mostly red alder but Douglas-fir is present (or was present prior to modern human alterations), use the Douglas-fir SPTH<sub>200</sub> for that soil polygon.

#### *Imputed SPTH<sub>200</sub> Values*

Four large urban areas (Seattle, Spokane, Tacoma, and Bellingham) lacked NRCS soil polygons; therefore, forest productivity information could not be mapped for most locations within those areas. Similarly, numerous soil polygons labelled as “Urban Land” lacked forest productivity information. For each of these four urban areas, WDFW calculated an imputed SPTH<sub>200</sub> by using an area-weighted average for 200-year site index values within a two-mile buffer around the perimeter. WDFW recommends the use of this imputed SPTH<sub>200</sub> as a guide for delineating RMZs in these urban areas. At the time of publication, WDFW had calculated imputed SPTH<sub>200</sub> information for those large urban areas. WDFW expects to continue to update the map.

#### *Dryland Ecosystems and Other Lands*

Not all soil polygons are forested, or have forest productivity information from NRCS; therefore, not all of them have associated SPTH<sub>200</sub> values. In addition, Benton, Franklin, Grant, and Adams counties had no forest productivity information in their NRCS soil polygons. These areas without SPTH<sub>200</sub> values were classified in one of two ways: as “dryland ecosystems”, or “other lands.”

---

<sup>14</sup> Imputed: estimated; a value assigned to something by inference from the value of the products or processes to which it contributes.

- WDFW approximated the area contained within “dryland ecosystems” using the Arid Lands Initiative study area boundary (Arid Lands Initiative, 2014) and have developed associated process steps that we recommend be used to derive RMZ widths (Volume 2, Section 2.2.3).
- The “other lands” comprise the remaining soil polygons and are small and dispersed across the landscape. These polygons include the NRCS soil map unit name, if applicable, and often represent soils that do not support tree growth, such as beaches and wetlands, as well as certain types of heavily modified sites like gravel pits. Please consult with a WDFW regional habitat biologist on deriving RMZs for “other lands” and consider following a similar process for delineation in dryland ecosystems.

## USING THE MAPPING TOOL

The mapping tool can be accessed from several locations:

- WDFW web site (<https://wdfw.wa.gov/species-habitats/at-risk/phs/recommendations>),
- Washington Geospatial Open Data Portal (<http://geo.wa.gov/>), and
- ArcGIS Online (AGOL) (<https://wdfw.maps.arcgis.com/apps/MapSeries/index.html?appid=919ea98204eb4f5fa70eca99cd5b0de1>).

The mapping tool consists of the statewide map with the four riparian datasets described above; user tools; and a sidebar explaining map contents, how to use the map, and links to supporting documents.

The four riparian datasets have unique colors indicating where the information occurs.

- Green: Area where SPTH<sub>200</sub> has been calculated.
- Orange: Areas where SPTH<sub>200</sub> values have been imputed.
- Pale brown: Dryland ecosystems where there is no tree height information.
- Beige: Places for which no SPTH site index information is available.

Tribal and publicly owned/managed lands federal and tribal lands are typically subject to different riparian regulations. Tribal, federal, and state lands are displayed in shades of grey. County-owned lands are shown in lavender, and city-owned lands are light blue.

The mapping tool contains the following tools (Figure A1):

1. **Zoom Slider:** zoom in or out on the center of the map.
2. **Home icon:** resets map to statewide extent.
3. **Target icon:** allows the user to zoom directly to their current location.
4. **Address Search:** zooms to a street address, place name, or latitude and longitude.
5. **Measurement:** use this to measure the distance between objects (e.g. edge of stream to another point), or to measure an area (square feet of an area surrounding a project site).
6. **Basemap Selector:** change the basemap to show a different view of the landscape: aerial imagery (default), topographic map, open street map, terrain with labels, and USGS national map.

7. **Legend:** displays the map layers currently visible. For example, map layers displayed at a site-specific scale will not appear in the legend when zoomed out to the statewide extent.
8. **Scale bar:** shows the scale that the map is zoomed to. At a statewide extent, the scale bar will show 0 to 60 miles. When zoomed to a scale where you can view the project area, the scale bar will show 0 to 100 feet or 200 feet.
9. **Coordinates:** latitude and longitude (decimal degrees) are shown where the cursor is located on the map.
10. **Panning:** move the map by placing the cursor over a desired location and dragging it to the center of the map display.

**Figure A1.** Tools available on the SPTH<sub>200</sub> and RMZ Online Map.

To zoom to a site location, use the Address Search tool or use a combination of the Zoom Slider and panning. (If using the Address Search tool, select the “ArcGIS World Geocoding Service” from the dropdown menu to the left of the search field for faster results.) Once the site is located, a click (on PCs) or tap (on mobile devices) of the cursor will open a popup window with information about that location. Be sure to review each window if multiple records are selected.

***The NRCS soil polygons form a complex mosaic across the landscape, so you must zoom in close enough to clearly see your project site.*** Clicking (or tapping, on mobile devices) on the map when it is zoomed out will result in erroneous returns of the SPTH<sub>200</sub> values. Below is an example of using these tools to obtain riparian information at a project site.

## MAPPING TOOL EXAMPLE #1

1. Start up the Online Map.
2. Type the project location into the Address Search tool (Figure A2). If the address is unknown, use a nearby place name or latitude and longitude.

This example uses 16018 Mill Creek Boulevard, Mill Creek, Washington.

3. Select the correct address from the drop-down menu or continue to enter manually. Click (on a **PC**) or tap (on a **mobile device**) the search button. The map will zoom to that location, shown as a small blue box and a popup titled "Search result" (Figure A3).

**Figure A2.** Using the Address Search tool.

**Figure A3.** Zoomed in aerial image of the site address.

4. Click (or tap) on the “X” in the Address Search tool to close the popup. Zoom and pan until you can clearly see where the project site is on the landscape (Figure A4).

In this example, the project site lies in a wooded area to the west of the address selected in the previous screen. We panned west to center the map display over the project site. In this screen, you can see the outlines of the soil polygons.

**Figure A4.** Adjusting the map display over the project site.

5. Click (or tap) near a stream on the project site. The outline of the soil polygon selected will turn blue, and a popup window will provide information about the  $SPTH_{200}$  (Figure A5). On a PC, the popup should automatically show (1) the  $SPTH_{200}$  in feet, (2) the species of tree it is based on, and (3) the reference study used to derive the height value. On a mobile device, tap the arrow on the right side of the popup to display this information.

**Figure A5.** Bringing up the SPTH<sub>200</sub> information at the project site.

In Example #1, the soil polygon for the project site only showed one tree species: Red Alder. Sometimes soil polygons will list more than one tree species, as shown in Example #2.

## MAPPING TOOL EXAMPLE #2

Example #2, the project site was at a different location. Steps 1-3 in Example #1 were repeated to zoom to the project site. For this site, the popup window for the selected soil polygon looked different:

- The upper left corner of the popup window says “(1 of 2)”; and
- There is a small arrow near the upper right corner of the popup window.

This means that this soil polygon has two different associated tree species. The first is Douglas-fir (see Figure A6a).

To view the information for the second tree species, click on the small arrow. The second tree species is western hemlock (see Figure A6b).

For project locations with multiple tree species, WDFW recommends using the largest SPTH<sub>200</sub> value, even if the largest tree species is not the most numerous (or even currently present) onsite.

**Figure A6a.** SPTH information for the first of multiple tree species at a given site.

**Figure A6b.** SPTH<sub>200</sub> information for the second of multiple tree species at a given site.

## APPENDIX REFERENCES: TREE SITE INDEX CURVES

The following twenty studies were used to determine  $SPH_{200}$  throughout the state:

The scientific rigor of this document was improved through the peer review provided by the Washington State Academy of Sciences, with coordination provided by Dr. Robert Bates. Draft versions of this document were reviewed by numerous staff in state agencies, including the Department of Ecology, Department of Natural Resources, Department of Commerce, Recreation and Conservation Office, State Conservation Commission, and Puget Sound Partnership. These reviews improved the document and we appreciate the helpful feedback. We also appreciate the reviews by federal and tribal entities including EPA, NOAA Fisheries, Northwest Indian Fisheries Commission, Columbia River Inter-Tribal Fish Commission, Upper Columbia United Tribes, and individual tribes. We express our appreciation for all local governments and individuals who provided feedback during our public comment period. Finally, thank you to Peggy Ushakoff for creating graphics that help us better portray the science.

While we acknowledge and appreciate all review comments, WDFW bears sole responsibility for the content of this document.

## Preface

**T**his Priority Habitats and Species (PHS) document of the Washington Department of Fish and Wildlife (WDFW) is provided in support of the agency's mission to preserve, protect, and perpetuate the state's fish, wildlife, and ecosystems while providing sustainable fish and wildlife recreational and commercial opportunities. WDFW works cooperatively with land use decision makers and landowners to facilitate solutions that accommodate local needs and needs of fish and wildlife. One of WDFW's important roles in land use decision making is that of technical advisor: we provide information about the habitat needs of fish and wildlife and the likely implications of various land use decisions for fish and wildlife.

The nine chapters of Volume 1 are a partial update of a 1997 document entitled *Management Recommendations for Washington's Priority Habitats: Riparian*. This document, called *Riparian Ecosystems, Volume 1: Science Synthesis and Management Implications* is a partial update because it addresses only aquatic species. Riparian needs of terrestrial species will be updated in the future. Until that update is complete, readers can consult the 1997 document, available at <http://wdfw.wa.gov/publications/00029/>, for information about riparian ecosystems and terrestrial species.

Priority Habitats are places that warrant special consideration for protection when land use decisions are made. For more information, see *Washington Department of Fish and Wildlife. 2008. Priority Habitat and Species List*, available at <https://wdfw.wa.gov/species-habitats/at-risk/phs>.

The PHS program provides land use decision support to clients such as local governments, tribes, government agencies, non-governmental organizations, and landowners. PHS consists of a PHS List, PHS Maps available at <https://wdfw.wa.gov/species-habitats/at-risk/phs/maps>, PHS Management Recommendations, and technical assistance from our regional habitat biologists.

This PHS document compliments a family of PHS documents including *Landscape Planning for Washington's Wildlife: Managing for Biodiversity in Developing Areas* and *Land Use Planning for Salmon, Steelhead and Trout: A land use planner's guide to salmonid habitat protection and recovery*, available at <https://wdfw.wa.gov/species-habitats/at-risk/phs/recommendations>.

# Chapter 1. Introduction

By: Timothy Quinn, Kirk L. Krueger, and George F. Wilhere

## 1.1. Document Description

**V**olume 1 is part one of a two-volume set. It contains reviews and syntheses of scientific literature for the purpose of informing the development of policies related to management of riparian areas and watersheds of Washington State. Volume 1 adds additional information to the science summarized in the PHS report titled *Management Recommendations for Washington's Priority Habitats: Riparian* (Knutson and Naef 1997).

Volume 1 was designed to answer the following three general questions:

- What is currently known about the key ecological functions of riparian areas?
- How do riparian areas and watersheds affect the freshwater habitats of fish and wildlife?
- How do human activities affect the capacity of riparian areas and watersheds to provide habitat for fish and wildlife in rivers and streams?

Volume 1 is intended to serve two goals. The first goal is to be a source of best available science (BAS) for understanding how riparian areas and surrounding

Chehalis River meander paths between 1938 and 2013/Ken Pierce, WDFW

watersheds affect ecological functions and aquatic habitats. The second goal is to provide a scientific foundation for management recommendations presented in Volume 2, which are consistent with Washington Department of Fish and Wildlife's (WDFW) mandate (RCW 77.04.012) to protect, preserve, and perpetuate Washington's fish and wildlife. Both goals also relate to WDFW's responsibility to support and provide technical assistance for conservation and protection measures necessary to preserve or enhance anadromous fisheries under the Growth Management Act (GMA; RCW 36.70A.172) and the Shoreline Management Act (SMA; WAC 173-26-221(5)(b)).

Volume 1 does not directly address instream flows as affected by water withdrawal for domestic and commercial uses, or instream water quality, both of which are regulated by the Washington Department of Ecology. However, because water quality is affected by land use, we discuss this issue in the context of riparian and watershed science. In addition, Volume 1 does not specifically address riverine wetlands, i.e., wetland associated with rivers and streams and commonly found in floodplains. Rather, riverine wetlands are usually considered part of riparian ecosystems, which are the focus of this document. Other specific wetland management guidance is available from Washington Department of Ecology (<https://ecology.wa.gov/Water-Shorelines/Wetlands>).

Volume 2 translates these science reviews and syntheses into land use guidance for local governments and other organizations to conserve watershed processes and riparian ecosystems in support of aquatic species and their habitats. The guidance presented in Volume 2 is not in and of itself "best available science." Rather, it represents the recommendations of WDFW as to how a local government could include the best available science in policies, plans, and regulations to protect riparian ecosystems and their associated aquatic habitats.

WDFW recognizes that natural resource management and land use policies must often balance competing ecological, economic, and social goals (Wilhere and Quinn 2018). In fact, one of WDFW's conservation principles is that management decisions should integrate ecological, economic, and social perspectives. This volume addresses only the ecology of riparian areas within the context of watershed conditions; it does not cover economic and social aspects. Determining an acceptable balance requires a political process involving stakeholders, local governments, tribes, and state agencies. Such a process would establish society's goals for freshwater habitats for salmon and other species of fish and wildlife, and lead to management for achieving those goals. This volume can help to inform that process.

### 1.1.1. Ecosystems

The ecosystem, a fundamental concept in natural resource management, can be defined as "a spatially explicit unit of the Earth that includes all of the organisms, along with all components of the abiotic environment" (Likens 1992). Throughout this document we use the term ecosystem composition to mean "the different parts (components) which something is made of" (Oxford Dictionary 2015). We define ecosystem structure as the "arrangement of and relations among the parts or elements of something complex" (Oxford Dictionary 2015). We define ecosystem function(ing) to include the first and second definitions of ecological function by Jax (2005): 1) the process, or the cause-effect-relationship underlying two or more interacting components, and 2) the sum of processes that sustain the system. Note that the definitions of functions we use here are broader and more inclusive than "functions" defined solely as ecosystem outputs that benefit humans, namely goods and services (Jax 2005; MEA 2005).

In this volume, we explicitly consider the composition, structure, and function of riparian ecosystems in the context of the surrounding watershed. This is especially important in light of the challenges of managing ecosystems sustainably and the risks associated with scientific uncertainty, i.e., the consequences of being wrong.

The composition, structure, and function of ecosystems describe the organization of biotic and abiotic elements and the processes occurring among elements. These concepts are closely related but not equally well studied nor understood. For example, describing an ecosystem's composition and structure is easier than describing its functions (Hunter et al. 1988; Noss 1992). Likewise, management objectives are often expressed in terms of composition and structure, not functions, because they are easier to characterize.

Composition and structure versus function have a chicken-and-egg relationship. That is, functions (processes) are in large part responsible for maintaining composition and structure, but some functions could not exist without an ecosystem's particular composition and structure. Myster (2001), for instance, argues that ecosystem structure can be defined as the minimal organization necessary for a function to operate. Others argue that managing for functions (Beechie and Bolton 1999) is likely to be more successful than managing for composition and structure because processes likely exert stronger influences on composition and structure than the other way around (Odum 1953), and processes are more directly affected by land use activities (Reid 1998). Furthermore, some land use laws or regulations stipulate no net loss of ecological functions, not no net loss of composition and structure (RCW 90.58, WAC 173-26-186, WAC 365-196-830), however, compliance is often determined through evaluating ecosystem composition and structure, not functions. Such conceptual ambiguity suggests that we consider the entire ecosystem, i.e., composition, structure, and functions, when studying riparian areas,

and furthermore, that land managers understand how composition and structure manifest ecological functions. The following chapters synthesize our review of the relationships among composition, structure, and functions of riparian ecosystems in the Pacific Northwest.

## 1.1.2. Riparian Ecosystems

WDFW has adopted the following conceptual definition of riparian ecosystems:

*Riparian areas are transitional between terrestrial and aquatic ecosystems and are distinguished by gradients in biophysical conditions, ecological processes, and biota. They are areas through which surface and subsurface hydrology connect waterbodies with their adjacent uplands. They include those portions of terrestrial ecosystems that significantly influence exchanges of energy and matter with aquatic ecosystems (i.e., a zone of influence).*

*Riparian ecosystem/Scott Fitkin, WDFW*

Riparian ecosystems are sometimes referred to by different names: riparian areas, riparian zones, or riparian habitats. To compound confusion, the “riparian zone” is sometimes identified as a distinctive area within riparian ecosystems (Sedell et al. 1989; Naiman et al. 1992; Steiner et al. 1994). Some definitions include the adjacent waters whereas others do not. Unless stated otherwise, we consider riparian area, riparian habitat, riparian corridor, and riparian ecosystem to be synonyms. Furthermore, our definition of riparian ecosystem does not include adjacent waters (i.e., rivers or streams) and recognizes the riparian zone as a distinctive area within riparian ecosystems. The riparian zone contains wet or moist soils and plants adapted to growing conditions associated with periodically saturated soils.

Recent definitions reflect common conceptual understanding and identify similar composition, structure, and functions, including distinct plant communities and soil types; disturbance regimes unique to fluvial systems; gradients in soil, vegetation, and microclimate that manifest an ecotone between terrestrial and aquatic environments; and essential interactions between terrestrial and aquatic ecosystems. Riparian areas are the loci of terrestrial and aquatic interactions, however, the exact boundaries of riparian ecosystems can be difficult to delineate

because: 1) ecosystems are not uniquely identified entities (Karr 1996); 2) the environmental heterogeneity of riparian areas is expressed in a variety of plant life history strategies and successional patterns; and 3) some ecosystem functions depend on environmental setting (Naiman et al. 1998).

Following Naiman et al. (1998), our definition of riparian ecosystem includes the active floodplain, including riverine wetlands, and the terraces or adjacent uplands that directly contribute organic matter or large wood to the active channel or active floodplain (Figure 1.1 and 1.2). Terraces and adjacent uplands that contribute organic matter or large wood are located in the “zone of influence.” The active channel is defined by the lower limit of continuous riparian vegetation (Naiman et al. 1998), and it may be delineated by absence of both moss on rocks and rooted vegetation (USFS 2008). The upper most elevation of the active channel is sometimes equated with the ordinary high water mark. The active floodplain is located between the active channel and adjacent terrace or hillslopes (Fetherston et al. 1995; Harris 1987). Depending on the watershed, the flood return interval of the active floodplain varies between 1 and 10 years (Wolman and Leopold 1957; Ward and Stanford 1995; Lichvar et al. 2006; Williams et al. 2009; BLM 2015).

Figure 1.1. A generalized diagram of the riparian ecosystem. The NRC (2002) states that, "Riparian areas are transitional between terrestrial and aquatic ecosystems and are distinguished by gradients in biophysical conditions, ecological processes, and biota. They are areas through which surface and subsurface hydrology connect waterbodies with their adjacent uplands. They include those portions of terrestrial ecosystems that significantly influence exchanges of energy and matter with aquatic ecosystems (i.e., the zone of influence)." The portion of the ecosystem characterized by moist soils and plants adapted to periodically saturated soils is the riparian zone. The width of the riparian ecosystem is typically based on riparian functions (i.e., wood recruitment to the stream in forested regions and the pollution removal function in dryland regions).

Riparian ecosystems are priority habitats in part because wildlife occurs more often and in greater variety in riparian areas than in any other habitat type. "Natural riparian corridors are the most diverse, dynamic, and complex biophysical habitats on the terrestrial portion of the earth" (Naiman et al. 1993). Although riparian ecosystems constitute a small portion of the surface landscape, approximately 85% of Washington's wildlife species are known to use riparian areas associated with rivers and streams (Knutson and Naef 1997). Of these, 170 species including 134 mollusks, 11 amphibians, 3 reptiles, 10 birds, and 9 mammals may be riparian obligates, i.e., require riparian habitat to survive (T. Quinn, unpublished). In addition, habitat for many upland and aquatic species is directly enhanced by

the presence of adjacent riparian areas. A principal reason for high fish and wildlife diversity is that riparian ecosystems are exceptionally productive. Riparian

*Western Toad Anaxyrus boreas egg strings/Scott Fitkin, WDFW*

ecosystems are characterized by the availability of water, milder microclimate, and relatively fertile soils. These factors enhance the productivity of plant communities and support a complex food web that includes a rich variety and abundance of fish, invertebrates, amphibians, plants, bacteria, fungi, reptiles, birds, and mammals (Cummins 1974; Johnson and Carothers 1982). It is not surprising then, that \$1.4 billion (57%) of \$2.5 billion spent to recover salmon in Pacific Northwest since 2000 has been directed at enhancing, restoring, and maintaining salmon habitat (e.g., large wood supplementation, riparian planting, fine sediment remediation, land acquisition) previously provided in large part by functioning riparian areas (NOAA 2015).

In addition to their essential role as fish and wildlife habitats, riparian areas provide other significant benefits to humans (Naiman and Bilby 1998; NRC 2002). Briefly, riparian areas help provide a variety of

ecosystem goods and services: provisioning services such as food and water; regulating services such as decreasing flood flows; supporting services such as nutrient cycling, sediment and pollutant filtering, and carbon sequestration; and cultural services such as recreational, spiritual, and other nonmaterial benefits (MEA 2005). These services provide real but often unquantified economic benefits to individuals and society; benefits that largely go unnoticed until they are lacking. According to the NRC (2002), protection and restoration of riparian areas should be a national goal because they have a major influence on achieving important national standards of the Clean Water Act, the Endangered Species Act, and flood damage control programs.

This document includes consideration of river-associated wetlands but does not consider other types of wetlands, which are covered by the Washington

Figure 1.2. Dryland Riparian Ecosystem. The riparian ecosystem consists of two zones: riparian and zone of influence. The riparian zone extends from the edge of the active channel towards the uplands. This zone includes areas where terrestrial biota and soils are influenced, at least periodically, by surface or subsurface waters. Beyond this is the riparian "zone of influence." This includes areas where ecological processes significantly influence the stream (diagram modified from USFS 2004).

Department of Ecology, or areas bordering marine or estuarine (brackish) waters despite the potential applicability of this work to those environmental settings. A 2009 review of riparian functions of marine shorelines is available at <https://wdfw.wa.gov/publications/00693>.

## 1.2. Scope of Volume 1

### 1.2.1. Riparian Ecosystem Management

**R**iparian ecosystem management is often couched in terms of maintaining riparian functions thought to be important to fish and wildlife and their habitats (e.g., Bolton and Shellberg 2001, Everest and Reeves 2007). Some commonly identified riparian functions are described in FEMAT (1993) and the Forests and Fish Report (DNR 1999). The riparian ecosystem functions we discuss in this document, including some associated compositional and structural elements, are organized by chapter:

- Chapter 2. *Stream Morphology*—the interplay of water, sediment, and vegetation on channel form and riparian areas
- Chapter 3. *Wood*—effects of wood on channel morphology and habitat, and the recruitment of wood from riparian areas
- Chapter 4. *Stream Temperature*—effects of hydrology and shading on the thermal regime of streams
- Chapter 5. *Pollutant Removal*—the interception or filtration of fine sediments, excessive nutrients, pathogens, pesticides, and other contaminants in overland and shallow subsurface flows
- Chapter 6. *Nutrients Dynamics in Riparian Ecosystems*—dynamics and fate of the primary macro-nutrients: nitrogen, phosphorus, and carbon
- Chapter 7. *Riparian Areas of the Columbia Plateau*

- Chapter 8. *Watersheds*—relationship of watershed-scale management to the goal of achieving beneficial effects for fish and wildlife

Riparian functions are affected and in turn affect aquatic and terrestrial systems at multiple spatial scales. We focus much attention on riparian functions at the site (e.g., stream reach or land parcel) scale for three reasons. First, riparian areas are disproportionately important, relative to area, for fish and wildlife and other ecosystem services (Naiman and Bilby 1998; NRC 2002). Second, local governments and individual landowners, important users of WDFW's PHS guidance, typically manage at the parcel scale. Most land use activity, outside of public lands, occurs at the site-scale on ownership parcels that are relatively small compared to the watershed in which they occur. Third, effective and efficient conservation of fish and wildlife habitats requires management at multiple scales and thus good site-scale riparian management is an essential complement to good watershed management (Chapter 8), although approaches at different scales can vary dramatically.

### 1.2.2. Watershed Management

Even when all riparian functions are protected, rivers, streams, and riparian ecosystems are not immune to the effects of upland management. To varying degrees, riparian and stream structure, composition, and function reflect land uses and conditions throughout watersheds.

Regardless of its size, no ecosystem is entirely closed. Upslope activities can considerably alter the magnitude and timing of stream flows; the mobilization, routing, and storage of sediment, wood, and fine organic matter; and the quality of water, thereby influencing riparian ecosystem functions (NRC 2002; Figure 1.3). Thus, the management of riparian ecosystems at the site or reach scale should be considered just one important part, not

the sole requirement, of holistic watershed management for the protection of fish and wildlife and other values. We include Chapter 8, which focuses on watershed-scale issues that are important to the management of aquatic systems as a whole, with the intent of increasing

the effectiveness of collective riparian conservation efforts. This chapter provides a conceptual framework that identifies the key watershed processes and their primary influences by, on, and through riparian areas and adjacent watercourses.

Figure 1.3. Conceptual framework for the hierarchical relationship of invariant, large-scale “process drivers,” the suite of watershed processes that are determined by these drivers, and the instream physical and biological responses to those processes. Multiple additional interactions between elements and levels are not shown on this diagram to emphasize the primary influences; but in any given setting, one or more of these secondary interactions may temporarily achieve equivalent importance. This framework embraces the definition of watershed processes from Stanley et al. (2011): “[t]he dynamic physical and chemical interactions that form and maintain the landscape and ecosystems.”

*Devil's Club* *Oplopanax horridus* is common in wet soils of western Washington riparian areas/Ned Pittman, WDFW

### 1.2.3. Science Synthesis

Chapter 9, *Science Synthesis to Management Implications*, of this volume summarizes important scientific finding from chapters 1-8 and provides a brief discussion of scientific themes that can inform thoughtful approaches to protecting aquatic systems.

### 1.2.4. Scope: Protection and Restoration

Protection and restoration of riparian ecosystems and watersheds are both essential for Washington's fish and wildlife, and especially for endangered and threatened salmonids. However, planning, management practices, regulations, and legal context for protection are different from those for restoration, and thoroughly covering both topics was beyond our scope. Thus, restoration is not explicitly incorporated in the scope of this document. Nevertheless, much of the science presented in this document can inform restoration activities. For instance, while this document does not review scientific literature on instream large wood placement, a common restoration activity, it does summarize large wood recruitment and reference conditions for the amount and size of instream large wood. Thus, the body of science that informs protection also helps to inform restoration, at least in terms of establishing resource goals and objectives.

## 1.3. Document Development

We employed the following approach to developing this document. We first established a Technical Advisory Group (TAG) of scientists from the region. Second, with guidance from the TAG, we conducted a literature review designed to inform the general state of knowledge regarding ecosystem protection and another literature review more focused on recent developments in riparian ecology and management. Third, we contracted with regional topic experts to author and co-author chapters. WDFW staff provided conceptual and technical guidance as possible. Finally, we subjected the draft final documents to several rounds of peer review. Each of these steps is discussed below.

### 1.3.1. Technical Advisory Group

The TAG helped provide overall science guidance, that is, contribute expertise and scientific perspective, provide important references and other sources of information, and review draft products. The TAG was composed of 13 individuals who were selected by virtue of their scientific expertise as opposed to affiliation with particular organization or stakeholder group. However, given the broad potential applicability of this document, it is conceivable that TAG members belong to one or more stakeholder groups. All TAG members were expected to attend three all-day meetings over the course of the project. Members of the TAG volunteered their time, except one who was paid a small stipend because she was employed by a non-profit organization. The first meeting was designed to introduce TAG members to the nature of the PHS update, to discuss different approaches to conducting a literature review and synthesizing new scientific information, and to

secure their ongoing commitment to helping WDFW meet high scientific standards. The second and third TAG meetings were designed to solicit review and feedback from TAG members on draft products. As part of their review process, we invited all TAG members to edit draft chapters and provide additional citations for WDFW's considerations. Although the TAG played a key role in advising WDFW on the science of riparian management and conservation, WDFW bears sole responsibility for the contents of this document.

## 1.3.2. Literature Review

We organized summaries around ecological functions including stream channel morphology, wood, pollution removal, nutrients, water temperatures, and watershed processes. Note that many of the issues we address here are directly or indirectly related to fish and wildlife habitats and other ecosystem services. We did not, however, explicitly consider cultural services that are important values for many stakeholders (e.g., spiritual, cultural and aesthetic values of riparian areas).

We enlisted the assistance of scientists with specific areas of expertise as technical advisors, authors, and informal and formal reviewers to help ensure that our summaries of pertinent scientific information were sufficiently accurate and inclusive. We were most interested in characterizing the state of knowledge and important, recent findings about each topic. That is, we tried to assess what we know, how well we know it, and what we do not know. The summary statements in each chapter are important to the development of management recommendations because they often identify important management challenges that are not well described in the published literature (e.g., the importance of habitat connectivity to fish population persistence). To this end, when appropriate, we encouraged authors to consider the broad body of scientific information and how it might be extrapolated to unstudied locales; in other words, to consider the

body of literature with regard to our ability to make reliable predictions.

Where information existed and as time allowed, we also attempted to summarize how riparian composition, structure, and functions differ among natural plant communities. In most cases, we used the broadest division called Major Vegetational Areas, which is made up of two groups in Washington State, i.e., Forested Regions and Steppe Regions (Franklin and Dyrness 1988). Regions can be further subdivided into forested zones (e.g., *Tsuga heterophylla* Zone) and steppe communities (e.g., shrub-steppe with *Artemisia tridentata*) that contain similar climax plant communities influenced by similar disturbance regimes. When information was available, for example, in the case of large wood in forested regions, we report that information at the finer division within the vegetation classification.

In addition, and as time and resources allowed, we summarized some potential effects of common land use activities on stream and riparian areas as a precursor to providing useful land use advice. We considered four general categories of land use: 1) urban, which includes commercial, industrial, urban, suburban, and rural development, 2) agricultural, which includes cultivated crops and grazing uses, 3) forestry, which includes timber management and associated activities such as

---

*Chapter 9 summarizes scientific findings from chapters 1 through 8 and includes a brief discussion of scientific themes that can inform thoughtful approaches to protecting aquatic systems.*

road building and maintenance, and 4) other activities (e.g., mining), which were not discussed due to the paucity of available research results.

We started this work by assembling topical literature reviews including Bolton and Shellberg (2001), Pizzimenti (2002), Bezener and Bishop (2005), Mayer et al. (2005), and Naiman et al. (2005). We compiled relevant literature cited in these review articles, from other reference materials we encountered, and from recommendations of TAG members. We also did an extensive literature search on computerized databases. We mostly focused our literature search on peer reviewed articles published after 1993, published in English, and conducted in proximity to Washington State. This last criterion was designed to focus on studies thought most relevant to Washington State's ecological conditions.

*The North Fork Skokomish River runs through mature conifer forests of the Olympic National Park/Tim Quinn, WDFW*

We also documented the type of review the study received according to RCW 34.05.271 (Appendix 1). Studies with no record of review were not considered further. As we (authors) reviewed the published literature, we noted important study findings that we believed would be especially useful for writing the PHS document. For empirical studies, our notes typically included the primary research questions or objectives, key results, management implications, and study limitations or assumptions. For literature reviews and syntheses, our notes summarized main conclusions by subject area. The intent here was to capture a sufficient level of detail for each paper so that we could use our collective notes as sources for writing the synthesis.

We found a massive quantity of literature related to riparian and watershed science despite focusing on information published after 1993. Due to the sheer volume of information, we could not cover all the literature in depth, so we covered those topics that were most relevant for management of riparian areas in Washington State. This document provides a comprehensive review on the current state of the science regarding certain riparian functions. Further, as described above, we enlisted the services of experts with specific areas of expertise as technical advisors, authors, and informal and formal reviewers to help ensure that our summaries of pertinent scientific information were sufficiently accurate and inclusive.

### 1.3.3. Peer Review

The peer review for Volume 1 consisted of a series of iterative steps, wherein we tried to gain as much agreement about the science synthesis as possible among those involved in the writing and reviewing process. Our intent was to provide the best available science. As described above, the TAG reviewed and often edited incomplete chapter drafts during the literature review and synthesis stage of the project. These draft syntheses were then given to topic experts to complete.

In cases, where WDFW lacked sufficient topic expertise, we provided stipends up to \$10,000 to outside authors (i.e., contractors) for completing a chapter. The steps involved in completion of drafts included adding one or more conceptual models describing the system and its functioning and a synthesis or summary of the important findings over the last approximately 20 years. These steps often entailed a series of editing and reediting by WDFW staff and contractors. Once completed by contractors and returned to WDFW, the drafts were reviewed a final time by TAG members. This last review by TAG members was to ensure that completion of the chapters was consistent with their earlier guidance and with their understanding of the literature. WDFW attempted to resolve all disagreement that occurred between contractors and TAG members and provided a written description of how those issues were resolved to both the contractor and the TAG. After final WDFW review, the document was submitted for review by the Washington State Academy of Sciences (WSAS).

We enlisted the WSAS to conduct the final, independent peer review of the PHS document. Modeled after the National Academy of Science, which is charged with providing independent, objective advice to the nation on matters related to science and technology, the WSAS provides expert scientific analysis to inform public policy making at the state level (WSAS 2015). The final peer review with the WSAS was also iterative. That is, WDFW in consultation with authors and TAG members, addressed WSAS comments, made appropriate changes to the document, and then discussed those comments with the WSAS in an attempt to resolve differences. This process proceeded until we reached agreement about scientific contents and conclusions.

# Chapter 2. Stream Morphology

By: Jane B. Atha, Mike Liquori, Kirk L. Krueger, George F. Wilhere, and Timothy Quinn

## 2.1. Introduction

**T**he composition, structure, and functions of lotic systems are largely due to dynamic interactions of water, sediment, wood, and riparian vegetation. The nature of these interactions is affected by topography (e.g., channel slope), flow regime, sources and characteristics of sediment, the size, strength, and density of riparian vegetation (Naiman and Bilby 1998), and the actions of some animal species, most notably the American Beaver *Castor canadensis* and salmon. The influences of water and channel slope on sediment results in channel patterns (i.e., straight, meandering, braided) (Leopold and Wolman 1957) and geomorphic zones (i.e., source, transport, depositional) (Schumm 1977) that occur somewhat predictably from headwaters to river mouth. Furthermore, variation in fluvial processes (e.g., frequency and intensity of floods) and controls (e.g., lithology, large wood, riparian vegetation) result in a wide range of channel forms or reach types that are often described based on their bedform (e.g.,

slope, sinuosity, distribution of sediment sizes, etc.) (Montgomery and Buffington 1997). These channel forms can be useful descriptors of aquatic species' habitats. Tributary junctions (Kiffney et al. 2006), natural disturbances (Frissell et al. 1986), and artificial structures (Stanford and Ward 2001) can create discontinuities in these general patterns.

The composition and structure of riparian vegetation affects channel morphology, which in turn affects riparian vegetation (Hupp and Osterkamp 1996; Corenblit et al. 2007; Osterkamp and Hupp 2010; Gurnell 2014). Additionally, channel morphology and the processes that shape it can be impacted by human activities (e.g., levees, dams, Beaver trapping), usually resulting in loss of habitats, reduced habitat diversity, and diminished habitat functions for aquatic species. Management actions such as bank armoring, channelization, and riparian vegetation removal tend to reduce natural variability of geomorphic processes, often amounting to stream habitat degradation greater than the sum of its parts.

Yakima River/Justin Haug, WDFW

Knowledge of the fluvial processes that affect riparian and aquatic systems is important for making sound policy and management decisions. This chapter provides an overview of water and sediment in fluvial processes, their interactions with riparian vegetation, and potential alterations of fluvial processes by human activities. We first describe a general conceptual model for considering how physical processes affect channel morphology. Next, we describe stream flow and sediment processes in more detail. We then consider the watershed-scale context that directly influences fluvial processes. Lastly, we review impacts of human activities on stream functioning, introduce the “riverscape” concept for the management of fish habitats, and describe some physical stream habitat associations of herpetofauna. Some related topics are discussed in other chapters. For example, see Chapter 3 for a description of fluvial process interactions with large wood and Chapter 8 for a thorough examination of influences and management that occur at the watershed scale.

## 2.2. Conceptual Context

**T**he concept of equilibrium is one of the most important ideas in fluvial geomorphology (Thorn and Welford 1994; Grant et al. 2013). The equilibrium concept posits that rivers tend to work toward long-term equilibrium (Gilbert 1877 as cited by Grant et al. 2013). *Dynamic equilibrium* describes a state of relative stability that results from the interaction of opposing forces (e.g., flowing water and substrate resistance). That is, over the long term and assuming that process drivers like climate and land use remain

unchanged (see Chapter 8), overall progression of the composition and structure of stream reaches in a watershed remains largely unchanged. A stream network may undergo significant changes during an extreme flood event, and yet return to equilibrium as smaller flows rework the sediment distributed by floodwaters to re-establish roughly the same relative abundance of stream reach types that existed prior to the flood event.

Lane (1955) conceptualized equilibrium within a stable channel as a balance among stream discharge, channel slope, sediment load, and sediment size (Figure 2.1). Lane’s conceptual model was described by Heede (1980) as:

$$Q_s D \propto Q_w S$$

where  $Q_s$  is sediment load (i.e., sediment discharge),  $Q_w$  is water discharge,  $D$  is sediment size, and  $S$  is channel slope.

What remains “in balance” over time are the processes of streambed degradation (erosion) and aggradation (sediment deposition). If an increase occurs in stream discharge, for instance, then the resulting increase in stream power can cause an increase in streambed degradation. The channel “adjusts” by decreasing channel slope, which reduces stream power and causes a return to the balance between degradation and aggradation. If a shift in stream discharge or sediment supply occurs, then the channel returns to equilibrium through adjustments in one or more other variables. However, persistent changes in one or more variables of sufficient magnitude may exceed a threshold that causes an abrupt shift to a new equilibrium state (Schumm 1979).

Figure 2.1. Lane's Balance illustrating the concept of channel adjustment (i.e., vertical aggradation or degradation of the streambed) in response to changes in water or sediment yield (from Dust and Wohl 2012).

While Lane's Balance is a useful conceptual model, it does not address complexity at the watershed scale nor the interactions between fluvial processes and riparian vegetation that affect channel morphology (Corenblit et al. 2007; Gurnell 2014) (Figure 2.2). These interactions are reciprocal and feedbacks exist between fluvial processes and vegetation composition and structure (Hupp and Osterkamp 1996; Osterkamp and Hupp 2010). Vegetation influences channel form and channel forming processes help shape riparian plant communities. Human activities that alter these interactions can cause significant changes to channel morphology and fish habitats.

Many geomorphic and ecosystem processes are coupled and occur in parallel at similar spatial and temporal scales. This results in mutual dependence between processes (Renschler et al. 2007). While such processes have received much attention from the scientific

community in the last fifteen years, a theoretical synthesis within a holistic conceptual framework is still needed to address how riparian management interacts with this complex system (Smith et al. 2002; Stallins 2006). Interdisciplinary research of these interactions could result in better predictability of impacts caused by management. From an ecosystem management perspective, the choice of spatiotemporal boundaries—often dictated by geomorphic processes—is of profound importance to conceptualization of the system and its ecologic processes (Post et al. 2007).

We frame the hydrologic and physical processes as they shape the riverscape from the context of equilibrium and mutual dependence among water, sediment, and vegetation.

Figure 2.2. Influences on channel morphology (modified from Naiman and Bilby 1998).

## 2.3. Streamflow Processes

**T**he pathways that water takes to reach a river exert a strong influence on the amount and timing of streamflow in the channel (Figure 2.3). Differences in the relative contributions of these pathways among locations and seasonal variability (e.g., presence or absence of snow) in environmental conditions produce a wide range of stream flow responses to precipitation events.

The fate of precipitation that is not lost through evaporation and transpiration is highly dependent on soil cover. Rain or melted snow that infiltrates the soil can flow downslope in the vadose zone (unsaturated),

above the water table as through flow, or below the water table as groundwater in the phreatic zone (saturated).

When precipitation rates exceed soil infiltration rates (Horton 1933) or when local soils are saturated (Dunne and Black 1970a, 1970b; Dunne 1978), water moves downslope as surface runoff. Surface runoff or overland flow remains outside the confines of a channel, and is most common where vegetation is sparse. Human activities that compact soil or destroy permeable, near-surface soil layers reduce infiltration capacity and promote overland flow. A second type of runoff, saturated overland flow, occurs at convergent zones (such as hillslope concavities) and is a combination of direct precipitation onto saturated areas and return flow from the subsurface as it becomes saturated (Wohl 2014) (Figure 2.3).

Figure 2.3. Illustration of different types and rates of downslope movement of water on a hillslope (modified from Ziemer and Lisle 1998, and Wohl 2014).

Runoff originates from variable source areas in response to precipitation and soil saturation conditions (Betson 1964; Hewlett and Nutter 1970). Conceptually, the amount of runoff within a single small drainage basin can be highly varied in space and time because many factors influence water infiltration and movement. Much of the variability in areas contributing water to the channel reflects the groundwater levels and activation<sup>1</sup> thresholds for lateral subsurface flow existing immediately after a precipitation event (McDonnell 2003).

Riparian vegetation influences preferential flow pathways in both surface and subsurface environments (Swanson et al. 1998; McDonnell 2003) and the manner in which surface flows create and maintain channel and floodplain morphology. During periods of active runoff, riparian areas quickly become saturated, and become

the first areas within the watershed to contribute runoff into the channel (McDonnell 2003). Riparian areas account for the majority of the runoff at the beginning of a flood event, whereas hillslopes contribute more as the runoff tapers off at the end of an event. Flow resistance provided by riparian vegetation and related organic material slows water velocities, reduces peak discharge, and lengthens a flood's duration (Tabacchi et al. 2000; Nilsson and Svedmark 2002).

In a reciprocal manner, stream hydrology plays a large role in shaping riparian vegetation communities. The rate at which the river water surface lowers after a spring freshet influences seedling germination and recruitment (Mahoney and Rood 1998). Thus vegetation species composition and age structure vary due to flow frequencies that determine sediment mobilization and effective discharge (Pike and Scatena 2010).

<sup>1</sup> Activation of subsurface water means that subsurface water is flowing, i.e., the velocity deviates significantly from zero. Activation threshold often refers to the amount of precipitation needed to activate subsurface flow.

Interactions between stream water and groundwater occur in the hyporheic zone. In other words, the *hyporheic zone* is the ecotone between a surface stream and deeper groundwater (Boulton et al. 1998). The extent of the hyporheic zone is determined by the volume of sediment stored within the channel and active floodplain (Moore and Wondzell 2005). Two-way exchanges of water occurring in the hyporheic zone are important in regulating hydrological, biogeochemical, and thermal processes (Krause et al. 2011), which strongly influence the volume, chemistry, and temperature of streamflow. Along this ecotone, upwelling subsurface water supplies the stream ecosystem with mineral nutrients while downwelling stream water provides dissolved oxygen and organic matter to organisms inhabiting the interstitial spaces of alluvial sediments (Boulton et al. 1998). The hyporheic zone can account for a fifth of the invertebrate production in an aquatic ecosystem (Smock et al. 1992). Water flows laterally from the hyporheic zone into alluvial sediment deposits, and can extend out more than 1.2 miles (2 km) in wide valleys and to depths of 33 ft (10 m) (Stanford and Ward 1988). Hyporheic flows can also affect riparian vegetation, although the interactions between riparian communities and hyporheic conditions are not well understood (NRC 2002).

Cape Creek, Lane County, Oregon/Jane Atha, WDFW

## 2.4. Erosion and Sedimentation Processes

### 2.4.1. Sediment Sources and Delivery

**S**ediment sources and delivery within a watershed can vary significantly depending upon geology, climate, landform, soil erodibility, vegetation, and the magnitude and frequency of dominant disturbances. Delivery of sediment to channels by surface erosion is generally low in undisturbed watersheds, but can vary greatly by year (Swanston 1991). Annual differences are caused by variation in weather patterns, changes in exposed surface area, and changes in the amount of erodible material. Sediment can move downslope in aggregates through mass wasting (mass movement, mass failure, or slope movement) categorized as landslides, debris flows, or heaves. Mass wasting events are typically seasonal as a function of soil moisture and freeze-thaw processes (Hales and Roering 2009). Soil on a hillslope will remain stable if the sum of the applied shear stresses does not exceed the sum of the shear strengths of slope materials (soils, roots, etc.). Mass wasting is initiated when shear stress on a material exceeds its shear strength threshold (Ritter et al. 2002). The volume of material generated from hillslope mass wasting events can be very large, and is often the predominant source of sediment and large wood delivered to streams in the Pacific Northwest (Swanson et al. 1982).

Sediment can also move downslope through gradual, diffuse processes such as rainsplash and rills that form from overland flow. Rainsplash takes place when raindrops loosen the soil particles making them more

*Skagit Valley agriculture/Jane Atha, WDFW*

susceptible to entrainment by overland flow (Furbish et al. 2009; Dunne et al. 2010). Overland flow can be concentrated into small, narrow, shallowly incised micro-channels that are carved into hillslope soils (Selby 1993). These channels, termed rills and gullies (with gullies being deeper) can form effective conduits for sediment erosion into stream channels (Wohl 2014).

Sediment delivered from riparian areas can be generated by mechanisms other than direct streambank erosion. Riparian sediment sources can be associated with treefall that results in the uprooting of trees (root throw; Hairston-Strang and Adams 2000; Liquori 2006). The primary causes of treefall include wind along newly created edges in riparian forest (Liquori 2006; Reid and Hilton 1998), undercutting streambank erosion, and large-scale disturbances such as fire or pest infestation. Root throw can provide direct sediment inputs to the channel (Lewis 1998; Reid and Hilton 1998; Gomi et al. 2005). Harris (1977) found that windthrow-related sediment production along a stream in coastal Oregon was responsible for 33 tons of sediment per mile of

stream per year (18.6 metric tons per kilometer per year) (as cited in Gomi et al. 2005).

Riparian vegetation can effectively trap and store sediment transported downslope from overland flow (Naiman et al. 2010). This topic is fully explored in Chapter 5, Pollutant Removal. Once the sediment is deposited in riparian areas, plant roots facilitate stabilization and continued storage of sediment (Allmendinger et al. 2005; Tal and Paola 2007).

## 2.4.2. Instream Sediment Transport and Deposition

Sediment that has entered the stream channel can be transported downstream as dissolved load, suspended load, or bed load. Dissolved load carries sediment within solution, which can be substantial in some rivers (Knighton 2014). The concentration of solute is highest in water entering the channel through subsurface pathways because slower rates of subsurface water

movement allow for longer reaction times with the surrounding environment. Solute concentrations through subsurface pathways tend to lessen with greater discharge (Wohl 2014). Suspended load refers to sediment carried as suspended particulates in the water, and originates predominantly from bank erosion and surface erosion from upland areas. The finest size fractions of suspended transport, known as wash load, are more likely to be supply limited, i.e., the amount in transport is limited by the amount available. In contrast, the coarser bed load, which consists of larger rocks that bounce along the channel bed, is typically limited by transport capacity of flowing water (stream energy). Bed load may not get suspended; it can roll and slide during low flows, saltate (bounce) at intermediate flows, and move as sheetflow during high flows (Wohl 2014). Bed load transport processes are surprisingly complicated because many factors, some of which interact, determine the threshold for movement. These factors include the range of sediment sizes, their spatial arrangement, and channel form within a reach (Knighton 1984).

Bedforms are bed undulations that result from sediment transport and deposition. Montgomery and Buffington (1997) classified stream channels based on common bedforms (i.e., cascade, step-pool, plane-bed, pool-riffle, and dune-riffle), their dominant sediment transport process, and behaviors of debris flows and instream wood. The role that sediment plays in aquatic habitat can differ dramatically among those classes. For example, sediment in headwater channels (often classified as cascade or step-pool) tends to be stored behind boulder and wood obstructions. In lower gradient channels, sediments become sorted into pools and riffles depending on instream wood load, gradient, and a wide variety of other factors (Benda et al. 2005; Gomi et al. 2005).

All bedforms are depositional features. Deposition occurs when the flow or shear velocity in the stream falls below the settling threshold velocity of the sediment particle. Settling thresholds are lower than entrainment

thresholds, and deposition can be localized or extended across a channel length depending on fluctuations in flow velocity (Wohl 2014). Riparian vegetation can be especially instrumental in facilitating deposition within channels and along banks (Tal et al. 2004). Establishment of riparian vegetation can initiate a positive feedback process as plants trap and stabilize sediments and organic matter that provides sites for germination of plants, which can then reinforce the development of floodplains, instream islands, and other landforms.

Erosional forces in the streambed can be increased due to topographic constrictions or locally steep gradients. Where hydraulic forces overcome surface resistance, channel incision can occur (Wells et al. 2009). Channel incision that occurs at the channel head, known as a headcut, results in vertical faces that separate upslope unchanneled environments from downslope channels. Headcuts that destabilize or incise an otherwise stable channel bed result in significant increases in sediment yield (Meyer et al. 1975; Bryan 1990). Headcuts can also occur as an upstream-migrating “step” in the channel bed that forms as a result of hydraulic scour, often from manipulations to the channel or flow conditions (e.g., culverts, diversions, etc.). This type of headcut can migrate upstream and change channel form for long distances.

---

*Establishment of riparian vegetation can initiate a positive feedback process as plants trap and stabilize sediments and organic matter that provide sites for germination of plants, which can then reinforce the development of floodplains, instream islands, and other landforms.*

A combination of field, experimental, and theoretical research has dramatically advanced our understanding of sediment transport dynamics as well as the role of vegetation in stream morphology. Sophisticated flume experiments and computational models have confirmed the importance and complexity of interactions among water, sediment, wood, and vegetation (Gurnell 2014). Recent modeling efforts have placed these phenomena on solid theoretical footings and have allowed researchers to explore scale dependence. We know much less about these interactions at small scales (single plant), however, understanding smaller scale phenomena is crucial to fully understanding longer-term and larger-scale geomorphic form and process (Gurnell 2014).

*Bank erosion along the upper Chehalis River/Jane Atha, WDFW*

### 2.4.3. Streambank Erosion

Streambank erosion is a geomorphic process that is integral to a watershed's natural disturbance regime and necessary for long-term ecological sustainability (Florsheim et al. 2008). Bank erosion is a key process for maintaining the structural diversity of aquatic and riparian habitats; it initiates community succession that promotes ecological diversity of riparian areas, and contributes coarse sediment to streambeds that is an essential habitat element for benthic invertebrates and spawning salmon. Bank erosion commonly occurs on the outside of river bends, but it can also occur in straight channels where changes in water or sediment supply cause channel incision. Instream large wood or mid-channel gravel bars that divert flows toward a bank (Florsheim et al. 2008) can also cause bank erosion. Local bank erosion is a naturally occurring process that is often indicative of a channel in dynamic equilibrium. Despite this fact, bank erosion at any scale is commonly misinterpreted as a sign of channel instability. Human disturbances can increase rates of bank erosion, and thus, understanding whether bank erosion is triggered by human activities or natural geomorphic processes is important for site-scale management (Polvi et al. 2014).

Two types of processes result in bank erosion: fluvial erosion and mass wasting (ASCE 1998). Fluvial erosion is the separation of sediments from a streambank's surface by the forces of flowing water. Fluvial erosion may destabilize riparian vegetation by exposing plant roots or undercutting vegetation (Florsheim et al. 2008). Fluvial erosion can eventually lead to mass wasting ("bank failure"). Mass wasting at streambanks is caused by scour of the streambed and bank toe that increases bank height and angle. When gravitational forces on the bank (weight of soil, water, and overlying vegetation) exceed the shear strength of the bank material, a portion of the bank collapses along a failure plane (Simon et al. 2000). Both types of bank erosion occur mainly during peak flows, but the association between flow magnitude and amount of bank erosion varies greatly among

*Building in danger from streambank erosion on Newaukum River/Kaysie Cox, WDFW*

watersheds. Wolman (1959, as cited in ASCE 1998), for instance, reported that significant bank erosion on a creek in Maryland occurred more than ten times per year during relatively small but frequent peak flow events. Studies of other alluvial systems have found that significant bank erosion was caused mostly by large floods with recurrence intervals of decades or more (ASCE 1998).

The stability of streambanks is influenced by soil characteristics, groundwater, and vegetation (Hickin 1984; NRC 2002). Mass wasting failure mechanics, for example, are quite different for cohesive and noncohesive soils (ASCE 1998). Adjacent surface waters or ground water affects pore water pressure, and positive pore water pressure destabilizes banks by reducing cohesion and friction amongst soil particles. Water in soil also adds mass, thereby increasing gravitational forces acting on a streambank. Bank failure often occurs shortly after flood waters recede because soils are at or near saturation and the laterally confining hydraulic pressure of the floodwaters decreases to zero (Rinaldi et al. 2004).

Vegetation may have mechanical and hydrologic effects on bank stability, and these effects can be stabilizing or destabilizing (Simon and Collison 2002; Langendoen et al. 2009; Pollen-Bankhead and Simon 2010). Soil is generally strong in compression, but weak in tension. Woody and herbaceous plant roots are strong in tension, but weak in compression. Consequently, the root-permeated soil of streambanks behaves as a composite material with enhanced strength (Simon and Collison 2002; Pollen and Simon 2005). However, the additional bank strength provided by roots is species dependent (Polvi et al. 2014). Simon et al. (2006), for instance, found that Lemmons's Willow *Salix lemmonii* provided an order of magnitude more root reinforcement of streambanks than Lodgepole Pine *Pinus contorta*. Dense root networks also physically restrain or bind soil particles. In addition, exposed roots on the bank surface increase channel roughness, which dampens stream flow velocities, thereby reducing fluvial erosion (Griffin et al. 2005; Gorricks and Rodríguez 2012). In fact, fluvial erosion of well-vegetated banks is 10 to 100 times less than erosion of unvegetated banks (ASCE

1998). Reduction of stream velocities by roots may also cause sediment deposition, which further stabilizes streambanks.

Vegetation has destabilizing mechanical effects as well (ASCE 1998; Simon and Collison 2002). The weight of vegetation adds a “surcharge”<sup>2</sup> load to soil. Hence, the weight of vegetation increases the vertical shear stress near a streambank and adds to the lateral earth pressure<sup>3</sup> at the streambank surface, however, these effects can be minimal relative to soil’s weight (Simon et al. 2006). Additionally, tall, stiff vegetation may impose destabilizing forces on streambanks during windstorms (ASCE 1998).

The hydrologic effects of plants on streambank stability are those that influence soil moisture. Through canopy interception, vegetation reduces the amount of precipitation that reaches soil. Transpiration, which extracts water from the soil column within the root zone, creates negative pore water pressures (matric suction) that increase soil shear strength (Simon and Collison 2002). Plants destabilize streambanks by facilitating infiltration of water into soil via flow pathways (“macropores”) created by live and decayed roots. In addition, stemflow tends to concentrate precipitation around the base of stems, creating higher local pore water pressure. The net hydrological effect of vegetation can be significant. Simon and Collison (2002), for instance, found in their study conducted in northern Mississippi that following a very dry period the stabilizing hydrological effect of tree cover was two times greater (220%) than tree cover’s stabilizing mechanical effect. However, this result was reversed following a wet period; the stabilizing mechanical effect of tree cover was 159% of tree cover stabilizing hydrological effect.

The bank stability function of riparian vegetation has important implications for riparian area management. FEMAT (1993:V-27) created a generalized curve of root strength versus distance from channel based on expert opinion informed by scientific literature. The radius of Douglas-fir *Pseudotsuga menziesii* root networks are highly correlated with tree crown radius (Smith 1964).<sup>4</sup> Hence, FEMAT (1993) assumed the contribution of root strength to maintaining streambank integrity declines at distances greater than one-half a crown diameter. Using linear regression, Roering et al. (2003) derived a power-law relationship for coniferous trees between root network radius and tree diameter. This relationship suggests that large diameter conifers (36 to 48 inches [91 to 122 cm] diameter breast height) have root network radii that measure 16 to 33 ft (5 to 10 m). Hence, in an undisturbed old-growth riparian forest, the full contribution of root strength to streambank stability is provided by trees within approximately 33 ft (11 m) of the streambank.

## 2.4.4. Lateral Channel Migration

Lateral channel migration affects sediment erosion and deposition, local topographic relief, flood inundation patterns, river planform, alluvial architecture, and riparian vegetation patterns, which in turn results in a complex arrangement of aquatic and riparian habitats across a river’s floodplain (Naiman et al. 1993). Lateral channel migration occurs through the processes of meander bend development, avulsions, and channel widening and narrowing (Rapp and Abbe 2003). These processes occur through fluvial erosion of intact bank material and mass failure of streambanks under gravity, followed by mobilization and transport of the disturbed material (Burckhardt and Todd 1998).

<sup>2</sup> A surcharge load is any load imposed upon the soil surface close enough to a streambank to cause lateral pressure to act on the bank. “Surcharge” denotes an extra force in addition to the weight of the soil.

<sup>3</sup> Lateral earth pressure is the pressure (i.e., force per area) that soil exerts in the horizontal direction.

<sup>4</sup> The ratio of root spread to crown width for small Douglas-fir and Western Hemlock (*Tsuga heterophylla*) (mean dbh about 13 inches [33 cm]) was reported by Smith (1964) to be about 1. Data in Eis (1987) for these same tree species suggest a ratio of about 2.

One mechanism of channel migration is meandering, which is one of the most common river-channel patterns (Güneralp and Marston 2012). Given time, and lacking physical obstructions, a natural unimpeded meandering channel can swing and shift across its valley in the downstream direction, completely disturbing the floodplain (Schumm 1977). The floodplains of meandering rivers are low-lying depositional features that store large volumes of sediment, and reflect the history of erosion and deposition of a river occupying the valley floor (Dunne and Leopold 1978). The time needed for a channel to migrate and occupy its entire floodplain is expressed as a “floodplain turnover rate,” which may take tens to thousands of years in western Washington. Beechie et al. (2006) found, for example, that braided channels in rivers of the Cascades and Olympic mountains had a turnover rate of 25 years. In contrast, O’Connor et al. (2003) estimated turnover rates for two large rivers on the Olympic Peninsula to be approximately 200 to 2000 years. The channel migration rates for the rivers in O’Connor et al.’s study ranged from 13 ft (4.0 m) to 42 ft (12.7 m) per year.

Sediment erosion and deposition patterns that result in channel migration are caused by complex flow patterns along meander bends. Water tends to develop a horizontal swirling flow as a result of greater roughness along the banks than in the center of the channel. This swirling flow, termed “helical flow”, is generated by the super elevation of the water’s surface as it flows along the outside of a bend (Callander 1978). Helical flow creates large cross-stream variation in velocity (Dietrich et al. 1984), and the reduced velocity and bed shear stress at the inside of a bend creates

pointbar deposition. In addition, pointbars deflect flow laterally toward the cutbank, creating topographically driven secondary flow that further induces an outward velocity shift toward the cutbank (Güneralp and Marston 2012).

Movements of individual meanders are described as: 1) simple migration (or translation), which is a downstream shift without significant shape change; 2) extension (or growth), where the amplitude of the bend extends by migrating across the valley; 3) rotation, in which the bend axis changes orientation; and 4) lobing and compound growth, where the bends become less regular and symmetrical (Hooke 1984). Individual bends along a meandering channel can have different styles and rates of migration, and typically deform and become asymmetrical with migration. Meander migration that increases the amplitude and tightness of bends can lead to a cutoff channel that creates a shorter flow path across the inside of a pointbar or a neck cutoff at the base of the bend. The increase in channel gradient from the cutoff causes it to become the main channel, and the longer flow path becomes a secondary or overflow channel on the floodplain. Secondary channels may function as side channels that are important rearing habitat for juvenile salmonids (Rosenfeld et al. 2008) or

*Chehalis River meander bend/Jane Atha, WDFW*

*Mid-channel bar/Jane Atha, WDFW*

oxbow lakes, which are habitat for amphibians (Henning and Schirato 2006). The increased habitat diversity for aquatic and riparian organisms can persist for decades to centuries depending on rates of sediment filling.

Another mechanism for channel migration is avulsion, which is the rapid abandonment of a river channel and the formation of a new river channel. Avulsions can occur with little erosion of the land between the old and new channel locations (Allen 1965; Butler 2004). An avulsion can cause rapid, dramatic shifts in channel location from one side of the valley bottom to the other, and can occur during a single flood event. Avulsions are often associated with aggrading channels, but this is not a necessary requirement (Tooth et al. 2007). Meander cutoffs, for example, are a type of avulsion not derived from aggradation. In the Pacific Northwest, wood jams often cause and mediate avulsions, acting to maintain a multiple-channel pattern. Wood jams can cause avulsions by plugging channels and diverting flow into a relict channel that then becomes the main channel (Collins and Montgomery 2002).

Along alluvial rivers, spatial and temporal patterns of riparian vegetation composition and structure are controlled by rates of channel migration and vegetation response to disturbance (Figure 2.4). As channels migrate laterally, pointbars create conditions for recruitment of early successional plant species. Over long periods, pointbar growth is followed by

the succession of terrestrial plant communities. Consequently, a pointbar may support a chronological series of successional stages arranged from youngest closest to the active channel to oldest farthest from the channel (Shankman 1993). A limited number of species consistently dominate the accreting edge of pointbar landforms, while progressively more species establish as the pointbar aggrades to a higher surface elevation (Meitzen 2009). Opposite these pointbars, eroding cutbanks expose and remove previously established mature vegetation, but also open edge habitat for colonization by new plant species. Kupfer and Malanson (1993) found that cutbank edge forests have higher stem densities and greater species richness than floodplain interior forests.

Lateral channel migration and related streambank erosion processes can pose risks to human communities located near rivers and large streams. Likewise, human actions intended to limit channel migration can degrade aquatic and riparian habitats. For these reasons, geomorphologists have developed protocols for determining the channel migration zone (CMZ). A CMZ includes the outer extent of historical channels, plus the area where future channel migration could occur over some time period (e.g., 100 years). CMZ delineation considers the historical migration zone, i.e., the area encompassing all historical channels; the avulsion hazard zone, i.e., areas not in the historical record that are at risk of avulsion; and the erosion hazard area, i.e., the area at risk of bank erosion from stream flow or mass wasting over the time horizon of the CMZ (Rapp and Abbe 2003). The CMZ typically encompass floodplains and some portion of terraces (landform remnants of the former floodplain). The CMZ also includes channels and terrace banks that are at risk of mass wasting due to erosion of the toe.

Lateral channel migration produces a spatially dynamic riparian ecosystem. Because the riparian ecosystem (i.e., the riparian zone and zone of influence) is defined by proximity to water, as the active channel moves back

Figure 2.4. A conceptual model of lateral channel migration processes and riparian forest responses (modified from Meitzen 2009). Arrows indicate the hypothesized directions of causal relationships. Brown boxes represent proximal processes leading to channel migration. White boxes are secondary processes. Green boxes depict structures. Blue boxes are biological responses.

Figure 2.5. Spatial relationships between the riparian ecosystem and channel migration zone (CMZ) over time. As the active channel moves laterally within the CMZ the riparian ecosystem moves with it. Time 1 and time 2 could be separated by days or centuries.

Quinault River/Jane Atha, WDFW

and forth across the CMZ, the riparian ecosystem moves with it (Figure 2.5). Consequently, over long periods of time, a riparian ecosystem will occupy different parts of the CMZ. Furthermore, when an active channel reaches the outside limit of its CMZ, the riparian ecosystem lies outside and adjacent to the CMZ. Hence, to maintain riparian ecosystem functions, management must anticipate and protect future locations of the riparian ecosystem.

## 2.5. Disturbances

### 2.5.1. Geomorphic Process Domains

**T**he spatial variability of sediment sources and the varying capacity of water to transport sediment result in a mosaic of different channel forms within a watershed. Channel forms

can be described by attributes such as bed and bank sediment size distributions, pool and riffle depths, bankfull widths, gradient, and sinuosity. The classification of channel forms has been refined over the last 30-40 years beginning with Schumm (1977), who distinguished a headwater production zone, mid-basin transfer zone, and downstream depositional zone. This longitudinal arrangement is also reflected in more recent work that defines geomorphic *process domains*. Process domains characterize differences in the types and frequency of disturbance events, and provide a way to represent spatial differences in disturbance regimes (Montgomery 1999).

Six common geomorphic process domains have been identified for forested watersheds of Washington State: hillslope, unchanneled hollows, debris-flow channels, bedrock-fluvial channels, coarse-bed alluvial channels, and fine-bed alluvial channels (Montgomery et al. 1996; Sklar and Dietrich 1998; Montgomery 1999). These process domains are important to distinguish since they

each function differently in terms of sediment dynamics and transport capacity. Note that although geomorphic process domains often occur in a regular longitudinal sequence, there are many exceptions in Washington State where this is not the case.

Hillslopes are unchannelized and are typically dominated by diffusive transport or rain-facilitated transport of sediment downslope. Unchanneled hollows are hillslope concavities that serve as sediment storage sites and source zones for hillslope mass movement (Dietrich and Dunne 1978; Montgomery et al. 2009). Debris-flow channels are dominated by mass wasting sediment dynamics but channel geometry may still be influenced by fluvial processes. Bedrock-fluvial channels have underlying exposed bedrock that limits boundary erosion. In these channels, overlying alluvium is transported by scour during higher flows, and transport capacity exceeds sediment supply, resulting in exposed bedrock. Coarse-bed alluvial channels are dominated by unconsolidated gravels, cobbles, and boulders and are more likely to be supply limited, rather than stream energy limited. Lastly, fine-bed alluvial channels have non-cohesive sand-sized sediment and are more likely to be transport limited by flow energy rather than sediment supply (Wohl 2014).

Using process domains, it is possible to identify within a watershed where different geomorphic processes, disturbance regimes, and responses to disturbance dominate, and predict riparian vegetation dynamics (Naiman et al. 2000; Polvi et al. 2011). Channel

morphology correlates well with bed gradient and sediment supply (Montgomery and Buffington 1997). The differences in the balance of hydraulic forces and available sediment among these channels likely lead to differences in overbank processes that can affect vegetation establishment, growth, and mortality. For example, in higher gradient channels, energy is expended on transporting sediment downstream and is not available to reshape the riparian area.

## 2.5.2. Natural Disturbance Regimes

From an ecological perspective, disturbances are relatively discrete disruptive events that change the physical environment or resource availability (Pickett and White 1985); thereby creating opportunities for other species to become established (Nakamura and Swanson 2003). Natural disturbances result in dynamic habitats of varying physical conditions that allow for a variety of species to coexist. Community succession theory recognizes that large-scale disturbances, such as low frequency, high magnitude floods, continually reinitiate community succession in riparian areas (Pickett et al. 1987; Corenblit et al. 2007). The cycle of disturbance and succession occurring throughout a watershed maintains compositional and structural diversity in aquatic and riparian ecosystems. Disturbances that influence streams and riparian areas include wildfire, floods, landslides, tree infestations by insects, and human-induced disturbances such as residential development, timber harvest, and road construction.

---

*Disturbances are relatively discrete disruptive events that change the physical environment or resource availability, and are essential for developing habitat to support native biota.*

Disturbance processes are essential for developing the range of habitat conditions necessary to support native biota (Swanson et al. 1998; Tabacchi et al. 2000). For example, the coarse sediments and large wood delivered to streams via mass wasting are thought to be essential components of freshwater salmonid habitats (Reeves et al. 1995). A natural disturbance regime can be characterized by frequency (how often), magnitude

(how big), duration (how long), and predictability. Wildfires of a given magnitude, for example, occur with a particular statistical probability in the absence of human manipulation of a watershed (Agee 1993). In general, smaller, frequent, and varied disturbances increase the heterogeneity of channel forms, leading to an environment that is more diverse and species rich (Kauffman and Martin 1989; Malanson 1993; Tabacchi et al. 2000; Everett et al. 2003). For example, the dynamics of stream channels that result from frequent, low intensity wildfires determine short-term patterns such as seed germination and animal foraging behavior (Hughes 1997). The influence of moderate and frequent disturbances such as fire (Wright and Bailey 1992) or insect-induced tree mortality (Mattson and Addy 1975) may lead to minor reductions in the riparian canopy, but more diverse habitat conditions that are generally beneficial for salmonids (Naiman and Bilby 1998). By contrast, disturbances that are large and infrequent tend to lead to widespread alterations that have larger and longer-lasting physical impacts. Large disturbances could cause a geomorphic threshold to be exceeded, and the resulting fluvial response could manifest a new geomorphic state with different physical conditions that support a different biological community (Hughes 1997).

Human activities can either dampen or amplify disturbance processes. While natural disturbance processes are ongoing, they are modified by human alterations (e.g., dams eliminate or dampen flood flows and land management can reduce the frequency and severity of fires). Too little or too much disturbance may have detrimental impacts on the physical structure of streams and riparian areas. For example, too little flooding can lead to cementation of the streambed or loss of riparian vegetation, especially in arid regions. Conversely, too much flooding caused by land cover change, for example, can lead to less habitat complexity due to excessive scouring of the channel. The past and current management of a site—and of its greater watershed—may alter the natural disturbance regime resulting in ecosystem states that did not exist historically.

Process domains within a watershed exhibit different disturbance regimes which manifest different aquatic and riparian ecosystems. Disturbances, and where they occur within a watershed, play key roles in structuring ecosystems. Important advances have shifted focus from single channel reaches and disturbance events to processes occurring at larger geographic extents over longer periods of time, that establish linkages between watershed-scale conditions and natural disturbance regimes (Naiman and Bilby 1998; Nakamura and Swanson 2003).

### 2.5.3. Human Alteration Impacts

Thus far, this chapter has largely focused on the hydrologic and geomorphic processes and their interactions with riparian area vegetation as they naturally occur within a watershed. However, human influences on channel form are ubiquitous, and therefore should be considered in management of riparian areas.

How a channel responds to human alterations of the landscape or riparian areas depends on its sensitivity and resilience (Brunsden and Thornes 1979).

*Narrow riparian buffers along Badger Creek/Jennifer Nelson, WDFW*

A sensitive channel reach changes in response to human alterations. A resilient channel reach also changes in response to human alterations but will return to its prior condition at some later time. The idea that some parts of a river are more or less sensitive or resilient is critical to predicting channel adjustments. For example, stream reaches with high transport capacity may adjust relatively quickly to an increase in upstream sediment yield but a similar change in sediment yield may cause significant changes in channel morphology in reaches with low transport capacity. The shape, hydraulics, and natural disturbance regime of a reach may indicate its sensitivity to anthropogenic disturbance. For example, a channel that is degrading (lowering bed elevation) may be more sensitive to riparian large wood additions than a channel that is in equilibrium. In addition, sensitivity to changes in hydrology is inversely proportional to channel gradient (Wohl et al. 2007). Hence, managers should anticipate that high gradient streams will be more sensitive to changes in stream flow than lower gradient streams. Other drivers such as the flow regime or controls such as lithology might also be used to determine a reach's sensitivity and resilience, and thereby inform management decisions.

## Forestry

An extensive body of scientific literature documents the effects of forestry on stream channels (see Foley et al. 2005; Scanlon et al. 2007; and Wohl 2013 for thorough reviews). Cutting of trees and road building associated with forestry can greatly increase sediment yields and affects water yields over multiple decades as vegetation recovers (Wohl 2014). Impacts from road networks—for logging and otherwise—are numerous and are discussed below. Changes in sediment supply and water yield due to logging can alter the streamflow, stream chemistry, and channel morphology of a stream reach (Liquori et al. 2008). In addition, the resilience of channels in response to such alterations can be quite variable. For example, Madej and Ozaki (1996) found that channel recovery (defined as returning to a former bed-elevation) after a sediment wave following extensive logging in Redwood Creek basin, Northern California varied from 8 years in one creek to 15 years in another. A third channel had not yet recovered.

*Clearcut hillside/Jane Atha, WDFW*

There is substantial agreement among scientists as to the potential magnitude and consequences of peak flow changes due to forestry. Grant et al. (2008) assessed the effects of forestry on peak flows and consequent channel response in the Pacific Northwest in a state of the science report. Their findings, primarily synthesized from long-term monitoring, show that responses are complex, and vary with runoff type (snowmelt, rainfall or rain-on-snow), local hydrology, harvest treatment, and channel type. The authors generally noted that geomorphic changes from harvest-related peak flow effects are limited to low-gradient channels (below 2% grade) and are generally minor as compared to other anthropomorphic impacts. Other literature reviews (e.g., Liquori et al. 2008; Grant et al. 1999) had similar conclusions.

*Big Beef Creek, Kitsap Peninsula/Ned Pittman, WDFW*

The degree to which forestry practices alter water and sediment yields depends on where the logging occurs within a drainage basin. In one study, logging at lower elevations in snowmelt-dominated basins of southwestern Canada caused little to no change in peak flow because of relatively small snowpack, whereas in the higher elevations the peak flow changed significantly (Whitaker et al. 2002). Similarly, characteristics such as climate, topography, and soils also determine landscape sensitivity to forestry. Several studies have shown that mean annual precipitation is a reasonable indicator of impact (e.g. Anderson et al. 1976; Coe 2006; CBOF-TAC 2008). A road network may deliver 20% of sediment to stream channels in areas with 22 in (500 mm) per year average precipitation compared with 50% of the sediment when precipitation exceeds 118 in (3,000 mm) per year (Coe 2006). In areas of high topographic relief, it is particularly challenging for researchers to differentiate channel adjustments induced by logging from change that would have occurred without interference (Marston 2008).

Conversion of riparian areas from forest to other land uses can cause channel narrowing and deepening (Anderson et al. 2004; Sweeney et al. 2004; Faustini et al. 2009). Furthermore, streams without riparian forests often exhibit channels with less wood that are narrower, deeper, have fewer obstructions, less variability in active channel width, higher proportions of run and glide habitats, and lower habitat diversity (Jackson et al. 2014).

## Road Infrastructure

Road networks are similar to stream networks in that they are often widely distributed, transport energy and material across a landscape, and have a high edge length per unit area enabling interaction with adjacent hillslopes (Jones et al. 2000). Stream networks and road networks commonly occur in similar densities in wet-climate forested mountains where logging has occurred (Wemple et al. 1996).

The biggest impact of unpaved roads on aquatic systems is sedimentation. Road construction and maintenance disturbs a layer of soil on the road tread, adjacent drainage ditch, and cutslopes that becomes easily eroded material (Megahan 1974). In conjunction with other loose material on roads, higher erodibility increases the total sediment yield from a road segment (Luce and Black 1999). In managed forests of Washington State, unpaved roads and trails are the most significant management activity that affects

sediment production and delivery into streams (Lewis 1998; Gomi et al. 2005; CBOF TAC 2008). Roads can initiate mass movements that tend to result in longer runoff zones and more sediment than their naturally occurring counterparts do (May 2002). Sediment generated from roads can be delivered to streams via ditches and gullies below cross-draining culverts that concentrate and route runoff. Road sediment production varies substantially with the type of surfacing material, road slope, mean annual precipitation, geology, traffic type and volumes, and road area (Cafferata and Munn 2002; MacDonald et al. 2004; Coe 2006). Roads and water crossings with improper design or maintenance are often the most significant sources of erosion and sediment delivery to streams in forested watersheds (Madej 2001; Cafferata and Munn 2002). Jones et al. (2000) found that unpaved roads continue to contribute sediment fines to channels long after harvested vegetation has reestablished.

## Agriculture

Agriculture, in the form of livestock grazing or crop production, can reduce and alter vegetation cover, compact soils, and reduce water infiltration. It can also increase runoff and sediment yield, and cause associated changes in streamflow, channel morphology, and channel stability.

Cattle grazing can severely degrade riparian areas particularly through vegetation reduction and trampling of streambanks. Grazing animals can create ramps

along streambanks and trails along the floodplain that enhance localized erosion (Trimble and Mendel 1995). Grazing-disturbed streams are usually characterized by a lack of overhanging banks, wide and shallow channels, smaller pool area, high sediment yields and turbidity, steep gradients, and channel beds typified by long stretches of glides or runs. Along streams with enclosures that kept cattle out of riparian areas, Magilligan and McDowell (1997) found that channel widths became narrower due to increased roughness by grassy riparian vegetation, which ultimately traps sediment leading to width reductions. The channel narrowing effects of grassy vegetation were also reported by Sweeney et al. (2004) and Allmendinger et al. (2005).

A common effect of planting crops is increased sediment yield and associated changes in channel pattern and stability (Wohl 2014). The magnitude of these changes is dependent on the type and extent of crops, as well as the topographic and soil characteristics at a site. Numerous case studies indicate that soil erosion from conventional agriculture exceeds rates of natural erosion by up to several orders of magnitude (Montgomery 2007).

## Urban/Suburban

Research on the effects of urbanization on sediment yield and channel response date back almost 50 years and is global in reach (Wolman 1967). The results of this research draw similar conclusions regarding the sequence of changes that occur within a drainage basin, with differences occurring only in the magnitude and timing (Chin 2006).

Erosion rates can reach up to 40,000 times pre-disturbance rates on land surfaces cleared for building that remain bare for up to a year (Harbor 1999). Construction sites can dramatically increase sediment yield from an urbanizing basin (Fusillo et al. 1977). For example, sediment production from Issaquah Creek

---

*Understanding a channel's state of equilibrium (or disequilibrium) and its potential future states is critical for restoration and protection of salmon habitats.*

*Mill Creek, Walla Walla, Washington/Jane Atha, WDFW*

watershed in western Washington had two- to five-fold increases when only 0.3% of its 55.6 mi<sup>2</sup> (144 km<sup>2</sup>) drainage area was under construction (Nelson and Booth 2002). Upon completion of construction, sediment yield usually decreases to negligible amounts as urbanizing areas are stabilized beneath roads, buildings, and lawns.

Research on the effects of urbanization on hydrology and flooding is also extensive, and dates back at least 50 years. Collectively, this research clearly shows that urban development, and associated increases in impervious surfaces, leads to larger and more frequent floods (Leopold 1968). The key metrics of change are peak discharge, lag time, flood frequency, and total runoff or water yield. Morphological adjustments have been studied in response to hydrologic changes, with most studies showing increases in channel width (Chin 2006).

## **Stream Channel Modifications**

Humans have been directly altering stream flow and channel form for centuries (Poff et al. 1997). Flow

regulation, through dams, reduces the size and variation of annual peak flows (Williams and Wolman 1984), increases minimum flows (Hirsch et al. 1990), shifts the timing of seasonal flows, and can alter diurnal flow fluctuations if the dam is used for hydroelectric power generation (Magilligan and Nislow 2001).

Dams can have dramatic effects on aquatic and riparian systems (Nilsson et al. 1997; Nilsson and Berggren 2000; Katz et al. 2005; Merritt and Wohl 2006). Dams disconnect the channel from the floodplain by reducing peak flows. This decreases or eliminates freshly scoured surfaces necessary for seedling establishment in riparian areas. Flow regulation can disrupt downstream transport of seeds to germination sites, and seedlings established on gravel bars may die from prolonged submersion when managed flows are higher than natural flows. Changes in sediment size distributions and moisture content can also adversely impact riparian vegetation. The cumulative effects on riparian communities downstream of dams can result in fewer plant species and lower plant density (Jansson et al. 2000).

Humans regularly alter channel form through dredging, channel straightening, removing instream wood or Beaver dams, building check dams, extending channel networks via canals, burying or laterally shifting inconvenient channels, and simply reconfiguring a channel to be more esthetically pleasing. (Wohl 2014). Levees are a direct form of channel alteration particularly ubiquitous in lowland rivers. Levees are mounds built parallel to stream channels that limit overbank flooding, and are also known as dikes or embankments (Petroski 2006). Levees severely reduce or eliminate channel-floodplain exchanges, facilitate higher magnitude floods, and exacerbate flooding in downstream areas without levees. Disconnection between the channel and floodplain reduces deposition of sediment and organic matter in floodplains, leading to loss of habitat, reduced animal abundance, and lower biodiversity in riparian areas (Hohensinner et al. 2004).

Lastly, humans can indirectly and severely alter channel form by introducing invasive, exotic species to riparian areas. Invasive plants may displace native riparian plants and thus impact streambank resistance to erosion and overbank sedimentation dynamics (Graf 1978; Allred and Schmidt 1999). Invasive riparian plants can also change patterns of water uptake and transpiration which in turn alter streamflows, subsurface water tables, nutrient cycling, and the quality and quantity of aquatic habitats (Schilling and Kiniry 2007; Hultine and Bush 2011).

## 2.6. Fish and Wildlife Habitat

### 2.6.1. Fish

The fisheries and fish ecology literature are replete with studies that report relationships between fish and physical habitat conditions. Such studies demonstrate the profound importance of instream conditions for fish and they have helped guide habitat management and restoration. For example, Nickelson et al. (1992) found seasonal differences in the use of pool and riffle habitat by juvenile Coho Salmon *Oncorhynchus kisutch* and suggested that additional pool habitats might improve their survival. Such correlative approaches have been expanded by considering shifts in habitat use within species and differential habitat requirements among species in attempts to identify optimal habitat type configurations (Rosenfeld 2003; Bain and Jai 2012). However, the success of such approaches has been limited by high spatiotemporal variability in, for example, habitat-density relations among streams (Dunham and Vinyard 1997; Dunham et al. 2002) that can be due to biotic and abiotic factors. Further, population statistics such as density can be a poor indicator of habitat quality (Van Horne 1983).

Juvenile Chinook Salmon *Oncorhynchus tshawytscha*/David Price, WDFW

Recent scientific advances regarding the protection and restoration of fish habitats (and habitats for other vagile aquatic species) include the following: 1) acknowledgement of the importance and frequency of fish movement (Schlosser 1991, 1995; Gowan et al. 1994), 2) greater acknowledgement of the importance of habitat heterogeneity and spatial variability in fish-habitat relationships (Torgersen et al. 2006), and 3) the concept of riverscapes (Ward 1998; Fausch et al. 2002; Allan 2004), which describes a dynamic mosaic of habitat types and environmental gradients that are characterized by high connectivity and complexity.

The riverscape concept expands on the classic stream continuum concept of Vannote et al. (1980) mostly by explicitly incorporating spatial and temporal heterogeneity, discontinuities, and connectivity between stream reaches (longitudinal), the stream and uplands (lateral), and the stream and groundwater (vertical). Fausch et al. (2002) provide several principles for effective research and management given the riverscape concept. These include: 1) conduct research (and management) at appropriate scales for the question, 2) the importance of physical and ecological processes are revealed at different spatiotemporal scales and processes will interact among scales, 3) rare or unique features can be very important, and 4) unintended consequences of habitat degradation propagate in all directions, including upstream. Cumulatively, these principles and the vast research that supported their development suggest that the spatial extent and temporal duration of research and management must be matched to the scales at which populations of species use habitat and at which suitable habitat conditions are created and maintained. Further, they emphasize the importance of maintaining and restoring longitudinal and lateral connectivity of stream systems (Sedell et al. 1989) to allow for proper functioning of habitat forming processes and maintenance and restoration of supplementary and complimentary habitats to account for expected variability in local suitability.

Conducting research and management that incorporates the riverscape concept is challenging because it often requires study at large spatial and long temporal extents as well as monitoring biotic and abiotic processes at fine spatial and temporal resolutions. Perhaps the best examples of such work in Washington are the Intensively Monitored Watersheds (IMW) projects that are designed to assess the efficacy of stream restoration for increasing the freshwater survival and production of salmon (Bilby et al. 2005). The IMW projects are conducted at the spatial extent of watersheds and over the course of several salmon life cycles. Important physical and ecological processes are monitored within and among individual stream reaches with the intent of identifying rare features and measuring changes in habitat complexity and connectivity (Bennett et al. 2016). This approach should yield reliable inferences regarding the efficacy of restoration efforts that can be used to inform decisions via adaptive management (Bennett et al. 2016).

## 2.6.2. Amphibians and Reptiles

Amphibians are less conspicuous inhabitants of instream habitats than fish, but in much of the Pacific Northwest, particular groups of stream-breeding amphibian species that include giant salamanders (*Dicamptodon* spp.), tailed frogs (*Ascaphus* spp.), and torrent salamanders (*Rhyacotriton* spp.) dominate fishless headwater

---

*The riverscape concept expands on Vannote et al.'s (1980) classic stream continuum concept by including lateral and vertical connectivity and incorporating spatial and temporal heterogeneity.*

*Coastal Tailed Frog *Ascaphus truei* in metamorphosis/Marc Hayes, WDFW*

streams. Headwater streams represent a large majority (up to 80%) of the overall stream network based on its length (Meyer and Wallace 2001). Stream-breeding amphibian dominance in headwaters partly reflects the flow conditions in headwater habitats and the suitable physical conditions those flows create. Amphibian abundance is highest in step-pool and cascade reach morphologies characterized by armored beds, stable bedforms, refuge spaces amongst coarse bed material, and reduced tractive forces as a result of tumbling flow (Dupuis and Friele 2006). For example, torrent salamanders, the only stream-breeding amphibian group that does not attach their eggs to rocky substrates, deposit and conceal them in the lowest flow headwater ends of streams and their tributaries; higher flow habitats will dislodge or damage their eggs. In contrast, giant salamanders and tailed frogs, which glue their eggs to coarse rocky substrates, use concealed oviposition sites in stable step structures typically found further downstream in the headwater network (Hayes et al. 2006). Stream-breeding amphibians seem to become less abundant below headwater streams at least in part because substrate and flow conditions that provide either oviposition or refuge sites become less frequent (Brummer and Montgomery 2003). Other conditions, such as predation by fishes, also play a role.

The freshets (high water events) in larger streams or rivers that have an alluvial floodplain, when coupled with wood, are also critical to both creation and maintenance of off-channel amphibian habitats (Amoros and Bornette 2002). Off-channel habitats comprise among the most important lowland stillwater habitats representing key breeding and rearing areas for the largest group of native amphibians (stillwater breeders) (Richter 2005) and the garter snakes (*Thamnophis* spp.) that feed on them. Such off-channel habitats are also critical rearing and foraging habitat for native turtles (Holland 1994).

## 2.7. Conclusions

**T**he interactions of water, sediment, wood, and riparian vegetation create complex channel morphologies and diverse aquatic habitat conditions. Reach-scale differences in sediment erosion, transport, and deposition result in a mosaic of aquatic habitat conditions within and among stream reaches.

Understanding a channel's state of equilibrium (or disequilibrium) and its potential future states is critical for restoration and protection of salmon habitats. Consistent with the idea of process domains, not all stream reaches within a watershed are equally sensitive or resilient to human land uses or other anthropogenic disturbances. Describing a channel's historical range of natural variability can aid in understanding a reach's potential response to human disturbance. A historical perspective may also aid in identifying biological communities that are in most need of habitat restoration (McDonald et al. 2004; Brierley and Fryirs 2009). By adopting a historical perspective, we may be able to move closer to the ecosystem composition and structure, and the resulting habitat heterogeneity, essential for fish and wildlife.

Historically, disturbance and successional processes were key drivers for the creation of aquatic habitats (Reeves et al. 1995). Now and into the future, both natural and anthropogenic disturbances will affect the creation, maintenance, destruction, and recreation of aquatic habitats. Management may most reliably result in high quality habitat when it emulates historical disturbances and their effects on a watershed (Poff et al. 1997). An idea offered by Naiman et al. (2000) is to base management on historical patterns of watershed conditions and natural disturbances. If flooding was a major natural disturbance in a watershed, then with empirical data and/or models on the extent to which flooding has affected the watershed, one could describe the dynamic equilibrium conditions of channels and floodplains over time, and then tailor riparian management to the unique conditions of that watershed. If wildfires followed by landslides were the historical disturbance pattern in a watershed, then watershed-scale, long-term forest management plans

might schedule timber harvests such that historical natural patterns are partially emulated (Reeves et al. 1995; Bisson et al. 2009). Emulating flood or wildlife disturbances for the benefit of salmon and other aquatic species will be a much more complicated project in residential (i.e., rural, suburban, urban) areas.

The importance of riparian ecosystems in maintaining channel, off-channel, and floodplain habitats is increasingly well supported by the scientific literature. In particular, the importance of longitudinal, lateral, and vertical connectivity to the quality of habitat conditions and the importance of riparian vegetation to stream channel stability are increasingly emphasized. Management of riparian ecosystems should consider connectivity among the geomorphic process domains, the influences of natural disturbance, the historical range of natural variability, and the inextricable influence that riparian vegetation has on geomorphic processes.

# Chapter 3. Wood

By: George F. Wilhere and Anne Marshall

## 3.1. Introduction

**T**he scientific study of wood in rivers and streams began about 50 years ago (Gregory 2003) and the vital ecological role of instream wood has been known for at least 40 years (Swanson et al. 1976). Over that 50 year period, the substantial quantity of research on instream wood has motivated numerous authoritative reviews of the scientific literature, such as Bisson et al. (1987), Maser et al. (1988), Gurnell et al. (1995), Bilby and Bisson (1998), Gurnell et al. (2002), Naiman et al. (2002a), and Hassan et al. (2005). A comprehensive, in-depth review of the ecology of wood in aquatic ecosystems is provided by Gregory et al. (2003). Although we have a solid understanding of wood's role in aquatic ecosystems and the pathways through which wood enters and moves through a stream network, some important questions remained unanswered.

*Wood, rocks, and roots – roughness elements that enhance habitat diversity by increasing hydraulic complexity/Jane Atha, WDFW*

This chapter focuses on the roles and recruitment of wood in aquatic ecosystems. It does not cover stream restoration using large wood. For information on that, see Dominguez and Cederholm (2000), Reich et al. (2003), Bisson et al. (2003), Carah et al. (2014), and Roni et al. (2014). For information on riparian forest management see Boyer et al. (2003) and Spies et al. (2013).

## 3.2. The Ecological Role of Instream Wood

Wood plays critical roles in the composition, structure, and function of riparian and aquatic ecosystems. In forested regions, wood is an important determinant of channel form and dynamics, especially in small streams (Montgomery and Buffington 1997; Bilby and Bisson 1998). However, the importance of wood's effects differs with channel dimensions, slope, sediment supply, and stream discharge (Gurnell et al. 1995). Large wood causes widening and narrowing, deepening and shallowing, stabilization and destabilization at different points along a stream or river channel (Swanson et al. 1976). The many effects of large wood create a variety of channel morphologies—dam pools, plunge pools, riffles, glides, undercut banks, and side channels—which provide a diversity of aquatic habitats. Pools are deposition sites for sediment and fine organic matter. Sediment is essential substrate for salmonid spawning, and stored sediments become mobilized over time to replenish downstream spawning areas.

Sediment and fine organic matter deposits are productive areas for invertebrates and are important food production sites for juvenile salmonids (Bisson et al. 1987). Pools provide rearing habitats and essential refuge from high flows for fish and other aquatic fauna. Instream large wood provides fish with cover from predators, and by increasing a water body's effective space, wood structures may increase fish densities (Bisson et al. 1987).

### 3.2.1. Small Wood

Wood is often divided into large and small size categories. Large wood is usually defined as having diameter greater than 4 in (10 cm) and length greater than 6 ft (≈2 m) (Bilby and Ward 1991; Schuett-Hames et al. 1999).<sup>1</sup> Small wood<sup>2</sup> consists of branches and other woody material not classified as large wood. Small wood plays essential and unique roles in lotic ecosystems. For instance, accumulations of small wood enhance a stream's retention of leaves and particulate organic matter (Gregory et al. 1991), which are vital food sources for many aquatic invertebrates. Small wood also effects channel morphology. Plunge and dammed pools are often associated with accumulations of small wood, and large wood with dense accumulations of small wood retain sediment significantly more frequently than large wood with sparse small wood accumulations (Bilby and Ward 1991).

Small wood exerts tremendous effects on hydrology and channel morphology through actions of the American Beaver *Castor canadensis* (Naiman et al. 1988). Beaver dams can store large quantities of sediment, reduce channel incision, remove excess nutrients from water, increase water retention and base flows, reduce peak flows, and by spreading flow events over longer periods,

increase groundwater recharge, and increase the salmonid habitat capacity of small streams (Pollock et al. 2015). Beaver dams consist mainly of mud and small wood. Published information on small wood sizes in dams of Beaver is lacking. However, Beaver most often forage on trees ranging from 1.2 - 3.2 in (3 - 8 cm) in diameter (Collen and Gibson 2001), and a large proportion of woody stems used as food are also used in dam construction (Barnes and Mallik 1996). In Maryland, Blersch and Kangas (2014) found that 98% of sticks (i.e., small wood) in a Beaver dam were less than 4 in (10 cm) in diameter and that 46% of those sticks were probably placed in the dam by Beaver. The other 54% of sticks in the dam were due to passive capture of transported wood. For more information on the role of Beaver and Beaver dams in aquatic ecosystems, see Pollock et al. (2015).

### 3.2.2. Roles of Instream Large Wood

The main role of large wood in aquatic ecosystems is large roughness elements (Bisson et al. 1987) (Figure 3.1). Roughness elements are obstacles in a channel that deflect flow and change its velocity. The size, shape, and strength of large wood make it very effective at redirecting hydraulic forces and the flow of materials (Figure 3.2), such as sediment and fine organic matter. Instream large wood increases hydraulic complexity, i.e., creates a wider range of flow velocities, which causes pool formation, streambed scour, sediment deposition, and channel migration. The net result is a diversity of aquatic habitats.

<sup>1</sup> Large wood is also known as large woody debris (LWD) or coarse woody debris. There is no universal definition of LWD. Another definition is greater than 4 in (10 cm) in diameter and greater than 3 ft (≈1 m) in length. The system of measurement used effects the size of large wood. The definition using English units (4 in wide and 6 ft long) results in a piece of smaller volume than the definition using metric units (10 cm wide and 2 m long).

<sup>2</sup> Small wood is also known as small woody debris or fine woody debris

The influences of instream large wood on aquatic ecosystems are a function of wood size relative to channel size. For instance, as much as 80% of pools in small streams can be associated with wood (Montgomery et al. 1995); however, the frequency of wood-associated pools decreases with increasing stream size (Bilby and Ward 1989, 1991; Montgomery et al. 1995). The latter relationship is due to the increased capacity of larger streams to transport large wood downstream.

In low order streams, "key pieces" of large wood affect channel morphology. Key pieces are defined as large wood that is independently stable within the bankfull channel (i.e., not held or trapped by other material) and have the potential to retain other pieces of large wood (WFPB 2011). Key piece size increases as channel width increases (Table 3.1). In large rivers, wood influences channel morphology through tangled accumulations of wood known as woody debris jams.

Stable structural features can promote channel stability (Sullivan et al. 1987). In large rivers, for instance, woody debris jams contribute to floodplain stabilization by initiating the formation of mid-channel bars that eventually become forested islands (Fetherston et al. 1995; Abbe and Montgomery 1996). In small streams, persistent large wood structures trap sizable amounts of sediment thereby increasing channel stability (Figure 3.3). Of all structures capable of storing sediment (i.e., wood, boulders) in small non-fish-bearing streams of northwest Washington, 93% were composed of large wood (Grizzel and Wolff 1998). Thirty to 80% of a stream's drop in elevation can be influenced by large wood (Keller and Swanson 1979), and log steps can reduce average channel gradients by 8 to 22% (Heede 1972). Reducing channel gradient dissipates stream power which mobilizes less sediment and increases sediment storage which can subsequently increase channel stability.

**Table 3.1. Minimum volume of large wood key pieces for different channel widths. Example dimensions for key piece length and diameter yield minimum volume. Diameter is measured at piece midpoint. One meter is approximately 3.3 ft.**

| Bankfull width (m)   | Minimum volume (m <sup>3</sup> ) | Example dimensions (m) |          |
|----------------------|----------------------------------|------------------------|----------|
|                      |                                  | Length                 | Diameter |
| 0-5 <sup>a</sup>     | 1                                | 2.5                    | 0.71     |
| 5-10 <sup>a</sup>    | 2.5                              | 7.5                    | 0.65     |
| 10-15 <sup>a</sup>   | 6                                | 12.5                   | 0.78     |
| 15-20 <sup>a</sup>   | 9                                | 17.5                   | 0.81     |
| 20-30 <sup>b</sup>   | 9.75                             | 17.5                   | 0.84     |
| 30-50 <sup>bc</sup>  | 10.5                             | 17.5                   | 0.87     |
| 50-100 <sup>bc</sup> | 10.75                            | 17.5                   | 0.88     |

<sup>a</sup> WFPB (2011), <sup>b</sup> Fox and Bolton (2007), <sup>c</sup> Must have an attached root wad.

Studies where wood has been experimentally removed from streams further reveal the significant role of large wood for storing sediment. For instance, Bilby (1981) measured a 72% reduction in sediment storage following removal of large wood from 575 ft (175 m) of streambed. Beschta (1979) observed a similar effect after woody debris dams were removed from a moderate gradient headwater stream in western Oregon where 6,500 yd<sup>3</sup> (5,000 m<sup>3</sup>) of sediment was lost from 820 ft (250 m) of streambed over a period of about 10 months.

Large wood can also cause transient channel instability. Keller and Swanson (1979) and Nakamura and Swanson (1993) describe stream reaches where large wood caused local erosion that increased channel width by more than 50%. In one case a woody debris jam increased channel width by 230%. These two studies also describe reaches where large wood caused lateral migration of the main channel and formation of side

Figure 3.1. Conceptual model depicting the effects of wood on fluvial systems and fish habitats. Arrows indicate the hypothesized directions of causal relationships; pluses and minuses indicate the hypothesized slope of each relationship. Brown boxes represent direct effects of wood on fluvial processes. White boxes are secondary processes. Green boxes depict channel structures. Blue boxes are habitat features. Diagram does not include most feedback loops.

channels. Over time, these types of disturbances create a shifting mosaic of aquatic and riparian habitats. Wood influences nutrient dynamics in two major ways: wood contains nutrients that are released through decomposition, and large wood influences the rate and timing of organic materials transport (Bilby 2003). The latter is the more important effect. Instream large wood traps and retains organic matter, such as leaves and other plant detritus, which are essential to the aquatic food web. Trapped organic materials are food sources for aquatic microorganisms, such as bacteria and certain fungi, and invertebrates, such as insects, crustaceans, and mollusks.

Figure 3.2. Sediment and nutrient storage and gravel bar formation behind large wood/Jane Atha, WDFW

Figure 3.3. Large wood altering channel morphology by creating dam pool, step drop, and plunge pool/Jane Atha, WDFW

The relationship between instream large wood and nutrient storage is well established. Larger quantities of wood per unit area in small streams lead to higher rates of storage of fine organic matter (Bilby and Likens 1980; Bilby and Bisson 1998; Brookshire and Dwire 2003). The mass of coarse particulate organic matter in streams in the McKenzie River watershed of Oregon was positively related to amounts of instream wood (Naiman and Sedell 1979). Bilby (1981) reported dramatic increases in downstream export of fine particulates during periods of high discharge following woody debris removal.

Carcasses of adult anadromous salmon provide nutrients to aquatic ecosystems (Cederholm et al. 1989; Reimchen et al. 2003). On the Olympic Peninsula, a positive correlation was observed between the number of Coho Salmon *Oncorhynchus kisutch* carcasses retained in streams and the amount of large wood in the stream (Cederholm and Peterson 1985).

By creating dams, instream large wood regulates water flow and storage. For example, surface water volume increased by 168%, five years after restoration of instream large wood in a coastal Oregon stream (Crispin et al. 1993), and third-order streams in Indiana with woody debris dams held surface water 1.5 to 1.7 times

longer than those with minimal large wood (Ehrman and Lamberti 1992, cited by Gurnell et al. 1995). Hydrological effects such as these may alter high flow events by reducing peak discharge and increasing the event's duration (Gurnell et al. 1995). Pools created by woody debris dams raise the water table in adjacent streambanks (Gurnell et al. 1995), and that affects riparian vegetation composition. For instance, at some sites, wet riparian soils may be maintained through seepage from pools, and wet soils are more suitable for Red Alder *Alnus rubra*, Red Cedar *Thuja plicata*, and Alaska Yellow Cedar *Chamaecyparis nootkatensis* than other tree species. Red Alder is known to contribute enormous amounts of beneficial nitrogen to soils and streams (Naiman et al. 2002b).

The hyporheic zone is the saturated sediment beneath stream channels and riparian areas where groundwater and instream water mix. Large wood diverts surface water flow into the hyporheic zone, and by trapping and storing sediments, large wood increases the volume of the hyporheic zone (Naiman et al. 2000). Greater hyporheic exchange can also reduce a stream's thermal sensitivity (Chapter 4).

### 3.3. Recruitment of Instream Large Wood

**T**he quantity of instream large wood is determined by the processes of wood recruitment, decomposition, and transport (Figure 3.4). "Recruitment" refers to the process of wood moving from the terrestrial environment to the stream channel. "Transport" refers to wood import to, movement within, and export from stream reaches. For comprehensive reviews of the dynamics of instream large wood, including decomposition and transport, see Benda et al. (2003), Bilby (2003), Gurnell (2003), and Piegay (2003).

### 3.3.1. Wood Recruitment Mechanisms

Large wood recruitment is often caused by bank erosion, windthrow, landslides, debris flows, snow avalanches, and tree mortality due to fire, ice storms, insects, and disease (Swanson et al. 1976; Maser et al. 1988). At any given site, more than one mechanism may contribute to recruitment. However, the dominant mechanism is determined by channel morphology, slope steepness, slope stability, forest composition and structure, and local wind patterns (Murphy and Koski 1989; McDade et al. 1990; May and Gresswell 2003; Johnston et al. 2011; Benda and Bigelow 2014). In large low-gradient rivers, for instance, wood is commonly recruited via bank erosion. Steep-sloped riparian forests along confined streams can recruit instream large wood via several mechanisms; however, landslides and windthrow are the dominant recruitment mechanisms in such settings (Nakamura and Swanson 1993; May and Gresswell 2003). Fox (2001) reported that smaller channels are likely to obtain a significant proportion of instream large wood by stem breakage and individual tree mortality due to insects or disease because smaller streams recruit less wood through lateral bank avulsion. Beaver recruit small wood to small, low-gradient streams (Pollock et al. 2003).

Instream wood originating from bank erosion increases as channel confinement decreases (Murphy and Koski 1989; Nakamura and Swanson 1993; Martin and Benda 2001; Johnston et al. 2011). In relatively unconfined third-order channels surrounded by mature and old-growth forests in British Columbia, bank erosion was the dominant route of large wood delivery, especially in wider channels (Johnston et al. 2011). Along Alaska's southeastern coast, bank erosion dominated large wood recruitment in alluvial channels, while windthrow was dominant in bedrock channels (Murphy and Koski 1989). Over a 63 year period, the Queets River (bankfull width = 420 ft [128 m]) recruited 95% of wood pieces

≥ 3 ft (1 m) in diameter through bank erosion that occurred as its channel meandered across its wide floodplain (Latterell and Naiman 2007).

The relative importance of each instream wood recruitment mechanism is highly variable (Table 3.2). Johnston et al. (2011) found tree mortality was the most common recruitment mechanism followed by (in descending order) bank erosion, windthrow, and landslides. In contrast, Murphy and Koski (1989) found that tree mortality was the third most common mechanism, and their rank ordering was bank erosion, windthrow, tree mortality, and landslides. Johnston et al. (2011) found that windthrow contributed 4% of instream large wood, but May and Gresswell (2003) found windthrow contributed 59%, on average. Benda et al. (2003) found that landslides contributed, on average, 17% of instream wood volume, but at the site-level, the contribution from landslides ranged from 0 to 66%. In the Oregon Coast Range, 65% of instream pieces of large wood and 46% of wood volume in a fourth order stream were delivered by landslide or debris flow (Reeves et al. 2003).

*Large wood suspended over water creates a refuge for fish from avian predators/Jane Atha, WDFW*

|                       | stem break        | --                            | 12                                            | --                              | --                               |
|                       | landslide         | 3                             | 1                                             | 29                              | 17                               |

1 = Murphy and Koski 1989, 2 = Johnston et al. 2011, 3 = May and Gresswell 2003, 4 = Benda et al. 2003

A site's recruitment mechanisms determine the magnitude and timing of wood recruitment events. Recruitment can be continual or episodic. In large, meandering rivers wood may be recruited through continual bank erosion. Soil creep along the eroding base of a hillslope may also contribute to continual wood recruitment. However, most wood recruitment occurs through episodic events such as floods, landslides, debris flow, or windstorms. For example, if a 100-year flood causes a river to migrate across its floodplain, then a huge volume of wood that would have taken decades to be recruited under smaller flows could be recruited overnight. In smaller confined streams, the main recruitment mechanism may be windthrow, which can recruit wood incrementally (single tree per event) or catastrophically (100s of trees per event).

### 3.3.2. Recruitment Distances

Forests adjacent to streams provide the majority of large wood delivered to stream channels (Murphy and Koski 1989; McDade et al. 1990), however, trees far removed from riparian areas may also be delivered via landslides (Reeves et al. 2003) or channel migration (Latterell and

Naiman 2007). Johnston et al. (2011) found that mean recruitment distances were greatest for wood entering by way of landslides, followed by (in descending order by distance) windthrow, stem breakage, falling of dead trees, and bank erosion.

Source distances are affected by channel geomorphology. The source distance of instream large wood differed significantly ( $P < 0.05$ ) when comparing alluvial streams to colluvial channels draining steep hillslopes in Oregon's Coast Range (May and Gresswell 2003). In this study, 80% of wood pieces and total wood volume originated from forests within 160 ft (50 m) of colluvial channels confined by steep hillslopes, whereas in unconfined alluvial channels, 80% of instream large wood originated from within 98 ft (30 m) of the channel (May and Gresswell 2003). Along steep second growth redwood forests in northern California, landslides resulted in recruitment distances extending over 197 ft (60 m) (Benda et al. 2002). In the Oregon Coast Range, large wood from pristine steeply sloped conifer-deciduous forest was delivered to a fourth order stream by landslide or debris flow from distances of more than 295 ft (90 m) upslope of the channel (Reeves et al. 2003).

Table 3.3. Recruitment distances of instream large wood from unmanaged old-growth conifer riparian forests.

| Location                         | Stream order or width   | Maximum recruitment distance      | Dominant recruitment process | Recruitment from intermediate distances                                                                                                                                         | Source* |

\* 1 = Murphy and Koski 1989, 2 = McDade et al. 1990, 3 = Benda et al. 2002; 4 = May and Gresswell 2003; 5 = Reeves et al. 2003, 6 - Latterell and Naiman 2007, 7 - Martin and Grotefendt 2007, 8 - Johnston et al. 2011.

† Tree height from Spence et al. (1996).

Source distances are affected by tree size. In one study, source distances for approximately 90% of instream large wood from mature and old-growth conifer riparian forest in western Washington and Oregon were within 85 and 130 ft (26 m and 40 m) of the streambank, respectively (McDade et al. 1990). The difference in source distances was largely attributed to taller trees in old-growth riparian forest (mean height = 189 ft [58 m]) compared to trees in mature riparian forest (mean height = 157 ft [48 m]). Likewise, recruitment distances measured in Alaska (e.g., Murphy and Koski 1989; Martin and Grotefendt 2007) are generally shorter than

those measured in Oregon (e.g., McDade et al. 1990; May and Gresswell 2003) because trees of the same species are generally shorter in Alaska than in Oregon (Table 3.3). Johnston et al. (2011) also found that large wood source distances increased with increasing tree height. For a more thorough discussion of factors affecting source distances see Benda and Bigelow (2014).

The stereotypic recruitment function describing the amount of instream wood versus recruitment distance is nonlinear (Figure 3.5). That is, areas closer to the

stream channel provide relatively more wood than areas farther from the stream channel. In southeast Alaska, for instance, 100% of large wood was recruited from within 98 ft (30 m) of the streambank, but 45% of large wood originated from within 3.3 ft (1 m) (Murphy and Koski 1989). Likewise, in a study from Oregon and Washington, 100% of large wood with an identified source was recruited from within 180 ft (55 m), but 50% of large wood with an identified source originated from 33 ft (10 m; McDade et al. 1990) (Table 3.3). The shape of the wood recruitment function, and in particular, the shape under different watershed and site-level conditions, is an important question for riparian forest management.

Although most wood is recruited from areas close to a stream (Table 3.2), areas farther from a stream cannot be discounted, especially along larger alluvial streams. Along a fourth order stream in Oregon, the sources for 65% of large wood originated on hillslopes prone to landslides and lay beyond 295 ft (90 m) from the stream channel (Reeves et al. 2003). In Washington, 50% of large wood in a fifth-order river was recruited by lateral channel migration from forests on floodplains and fluvial terraces that lay beyond 300 ft (92 m) from the riverbank (Latterell and Naiman 2007).

### 3.3.3. Wood Recruitment in Intensively Managed Forests

An important question for riparian area management is how does wood recruitment in second-growth or intensively managed forests differ from recruitment in unmanaged, “natural” riparian forests? The answer to this question is essential for understanding the effects of contemporary forest management on fish habitats, however, useful answers are difficult to obtain because forest practices today are much different from those of the past.

The current conditions of instream wood and riparian areas in second-growth forests are the result of past management, and over the past 100 years management practices have changed dramatically. In the early 20th century splash dams were built on small streams to sluice logs downstream (Bisson et al. 1987), a practice that flushed naturally occurring large wood from the channel. During the 1950s and 1960s wood was routinely removed from streams to “improve” fish passage (Sedell et al. 1988), and this practice continued until the 1980s (Bilby 1984). Until the 1970s, logging to the streambank was common in Oregon

Figure 3.5. Distribution of source distances from tree origin to streambank. Empirically derived curves for old-growth conifer, mature conifer, and mature hardwood stands in western Oregon and Washington (from McDade et al. 1990). Empirically derived curves based on large wood with an identified source. One meter is equivalent to 3.3 feet.

and Washington; a practice that changed shortly after passage of the Clean Water Act of 1972. From 1987 to 2000, the Washington Forest Practices Rules required 23 to 65 trees per acre in riparian areas (WFPB 1987). In contrast, old-growth riparian areas may have 160 or more trees per acre (Acker et al. 2003). The current forest practices rule (WDNR 2005) require much wider stream-side buffers with much higher tree densities in riparian areas than previous rules. The current regulations should result in a stand basal area equal to that of a mature conifer forest when the riparian stand is 140 years old. In short, over the past 100 years, riparian areas in intensively managed forests of Washington have been subjected to many different types of management, and over the next 100 years these same riparian areas will change dramatically.

Past forest practices are known to have severely degraded instream wood (Bilby and Ward 1991; Ralph et al. 1994), but current forest practice regulations are expected to improve instream wood (WDNR 2005). Whether current regulations will result in enough instream wood to create fish habitats that meet policy goals is unknown, and resolving that issue will be difficult until riparian areas attain their desired future conditions a century or more from now. Nevertheless, theoretical and empirical evidence suggest two main differences in large wood recruitment between second-

growth, intensively managed forests and unmanaged mature and old-growth riparian forests.

First, the size of wood recruited from intensively managed forests is smaller than wood recruited from old-growth forests. Benda et al. (2002) found that the diameter of wood recruited from old-growth sites was, on average, up to twice the diameter of wood found in 50-year-old second-growth sites. Czarnomski et al. (2008) found significantly higher numbers of large wood pieces in stream segments adjacent to unmanaged mature and old-growth sites than in segments adjacent to 30- to 50-year-old intensively managed sites. From a theoretical perspective, these results are unsurprising—the dominant trees in a 200-year-old stand are much larger than the dominant trees in a 50-year-old stand. A similar relationship was also reported by McDade et al. (1990) who found that the size, both length and diameter, of instream large wood was related to forest age—wood was significantly smaller in younger forests (i.e., unmanaged mature forest versus old-growth forest).

Second, both theoretical models and empirical evidence show that maximum wood recruitment distances for intensively managed forest are less than the maximum recruitment distance for old-growth forests (McDade et al. 1990; Robison and Beschta 1990; Benda and Bigelow 2014). Again, these results are due to relative tree sizes—taller trees can contribute large wood from longer distances. The models show that the maximum recruitment distance for large wood is slightly less than the height of dominant trees; however, these models do not incorporate the recruitment processes of landslides and lateral channel migration which could substantially lengthen the maximum recruitment distance. For instance, in Benda et al. (2002) the theoretical maximum recruitment distance for their sixteen 50-year-old second-growth sites was about 98 ft (30 m), but due to landslides two sites had large wood recruited from beyond that distance—105 ft (32 m) and 210 ft (65 m). The results of Benda et al. (2002) and Benda and

---

*Past forest practices are known to have severely degraded instream wood, but current forest practice regulations are expected to improve instream wood. Whether current regulations will result in enough instream wood to create fish habitats that meet policy goals is unknown.*

*Bank erosion recruits large wood into stream/Ned Pittman, WDFW*

Bigelow (2014) also show that regardless of stand age or management, recruitment distances are primarily determined by recruitment processes. Riparian areas where bank erosion is the dominant process will, on average, have shorter recruitment distances, riparian areas where landslides dominate will have longer recruitment distances, and areas where other forms of tree mortality (e.g., windthrow, suppression, disease) dominate will have intermediate recruitment distances. In short, spatial variability in large wood recruitment is a function of many factors, including stream size and channel morphology, forest management, and natural disturbances such as landslides, floods, and windthrow.

## 3.4. Abundance of Instream Wood

### 3.4.1. Forested Regions of Washington

**T**he abundance of instream large wood was much greater historically than it is today, especially in large rivers. One hundred fifty years ago, some woody debris jams on large rivers were nearly 1-mile-long (Sedell and Luchessa 1981), but

these impressive natural structures were cleared for purposes of river navigation. For instance, during the latter part of the 19th century, over 5,500 pieces of wood between 5 and 9 ft (1.5 and 2.7 m) in diameter were pulled from a 50-mile (80-km) section of the Willamette River (Sedell and Luchessa 1981). Collins et al. (2002) estimated that wood in some lowland Puget Sound rivers was 10 to 100 times greater prior to European settlement.

In contrast to large rivers, the abundance of large wood in small streams of unmanaged watersheds may still be representative of historical conditions. Fox and Bolton (2007) studied the quantities of instream large wood in natural, unmanaged forested watersheds in Washington. Ninety-six percent of their 150 sites had a stand age between 200 and 800 years (Fox 2001). In these watersheds, the processes of recruitment, decomposition, and transport were presumably undisturbed by human activities. Their findings, which are presented for forest zones and channel widths, could serve as reference or target conditions for instream large wood (Table 3.4).

### 3.4.2. Non-forested Regions of Washington

Fox and Bolton (2007) studied forested watersheds in forested regions (*sensu* Franklin and Dryness 1988), and, in fact, nearly all we know about instream wood is based on studies conducted in forested watersheds. This is unfortunate because our knowledge of instream wood for non-forested regions of Washington, such as semi-arid grasslands (i.e., steppe or Palouse) and shrub-steppe, is limited. Nevertheless, instream wood was likely to have been more abundant than it is today for two reasons.

First, in basins with headwaters in forested regions, such as the Yakima, Wenatchee, and Walla Walla basins, wood was transported downstream to shrub-steppe

and grassland streams. This process is known to have occurred in other semi-arid and arid regions of the United States. Minckley and Rinne (1985) present historical evidence for the movement of large wood in rivers of the desert southwest: wood originated in forested headwaters, moved sporadically through desert riparian areas during flood events, and was ultimately deposited at the mouth of the Colorado River in Mexico. Minckley and Rinne (1985) identify interception of large wood by dams as a major cause of large wood reduction in semi-arid and arid river basins. At artificial reservoirs in eastern Washington, such as Keechelus, Kachess, Cle Elum, Bumping, Clear, and Rimrock lakes, large wood that could potentially interfere with dam operations is removed and burned (W. Meyer and B. Renfrow, Washington Department of Fish and Wildlife, personal communications). Some small water diversion dams do the same with large wood. This practice diminishes the quantity and quality of fish habitat in the Yakima and Tieton rivers, especially in their semi-arid shrub-steppe sections.

Second, riparian areas in grassland and shrub-steppe regions are inhabited by a wide variety of woody plants—Black Cottonwood *Populus balsamorhiza*, Quaking Aspen *Populus tremuloides*, White Alder *Alnus rhombifolia*, Thinleaf Alder *Alnus incana*, Water Birch *Betula occidentalis*, Black Hawthorne *Crataegus douglasii*, and Yellow Willow *Salix lutea* (Crawford 2003), and the historical abundance of woody plants in riparian areas is thought to have been much greater than it is today (Wissmar et al. 1994; Kauffman et al. 1997; Wissmar 2004). Reductions in woody plant abundance are mainly due to hydrological changes caused by water diversions for irrigation (Jamieson and Braatne 2001) and livestock grazing. Restoration projects can indicate the density of woody plants that historically existed in riparian areas prior to intensive livestock grazing. Only two years after the cessation of grazing within riparian areas in northeastern Oregon, the mean crown volume of willows and Thinleaf Alder tripled in size and that of Black Cottonwood increased 9-fold (Case and Kauffman

1997). Furthermore, shrub density increased by 50%. One possible reason for the severe impacts of grazing is that riparian vegetation in the semi-arid grassland and shrub-steppe regions of Washington evolved with little grazing by large herbivores (Mack and Thompson 1982).

With the exception of Black Cottonwood, woody plants in grassland and shrub-steppe regions do not contribute key pieces of large wood to stream channels (Table 3.1).

Historically, much wood in stream channels of semi-arid regions was likely to have been small wood, and much of that small wood may have been recruited to and stored in the channel through Beaver activity. Prior to 1864, Beaver are known to have been abundant in the shrub-steppe region of central Oregon, and the eradication of Beaver from central Oregon is thought to have caused a cascade of effects: gradual disintegration of Beaver dams led to incision of streambeds, lowering of water

Table 3.4. Distributions of large wood per 100 m of stream channel by forest regions in Washington State and by bankfull width (BFW) class (Fox and Bolton 2007). Large wood was defined as pieces exceeding 10 cm (4 in) in diameter and 2 m (≈6 ft) in length. Key piece sizes are defined in Table 3.1. One meter is approximately 3.3 feet.

| Forest zones                                                                                                                                                 | BFW Class (m) | 75th Percentile                         | Median | 25th Percentile |

Wood jams are habitat features and are less common now than they were historically/Ned Pittman, WDFW

tables, loss of riparian vegetation, and subsequently deeper incision of channels (Buckley 1993). According to Pollock et al. (2007), the exact mechanism that caused widespread incision of streambeds remains uncertain, however, incision almost invariably coincided with widespread trapping of Beaver and the onset of intensive livestock grazing.

For the semi-arid grassland and shrub-steppe regions of Washington, we currently lack data with which to describe reference conditions for instream wood and for riparian plant communities. Historical reconstruction using General Land Office survey notes and historical photos is one way to develop qualitative descriptions of riparian plant communities (McAllister 2008); however, more quantitative descriptions would benefit development of management objectives. Much remains unknown about historical conditions of riparian areas in non-forested regions.

## 3.5. Fish, Wildlife, and Instream Wood

**A**uthoritative reviews of the scientific literature regarding relationships between instream wood and fish or wildlife species have been written by Bisson et al. (1987), Benke and Wallace (2003), Dolloff and Warren (2003), Zalewski et al. (2003), Steel et al. (2003), and Wondzell and Bisson (2003). Certain small mammal and bird species are

known to be associated with wood in stream channels (Steel et al. 2003). However, we discuss only fish, amphibians, reptiles, and invertebrates; taxonomic groups known to have strong associations with instream wood.

### 3.5.1. Fish

For salmonids, especially juvenile Coho Salmon, there is no more important structural component than instream wood (Bisson et al. 1987). In Puget Sound lowland streams, measures of salmonid rearing habitat were strongly linked to instream large wood abundance (May et al. 1997). In headwater streams, step pools formed by large wood were important for Dolly Varden *Salvelinus malma*, juvenile Coho Salmon, steelhead, and Cutthroat Trout *Oncorhynchus clarkii* in reaches with gradients less than 4% to greater than 10% (Bryant et al. 2007). Adult spawning Sockeye Salmon *Oncorhynchus nerka* densities were positively correlated with cover provided by large wood and undercut banks, pool area, and large wood (Braun and Reynolds 2011). The instream abundance of juvenile salmonids often is directly related to the amount of large wood (Murphy et al. 1986; Bisson et al. 1987). Stream reaches where large wood was artificially added were used by higher densities of juvenile Coho Salmon in summer and winter, and Cutthroat Trout and steelhead in winter in 30 western Oregon and Washington streams when compared to reaches where large wood was not enhanced (Roni and Quinn 2001). Spawning Coho Salmon abundance increased after instream wood structures were restored (Crispin et al. 1993). A study in British Columbia found that the biomass of yearling and older salmonids was positively correlated with stream pool volume ( $R^2 = 0.92$ ) and that over 70% of pool volume was formed by large wood (Fausch and Northcote 1992).

Large wood provides both direct and indirect benefits to fish (Bisson et al. 1987). Indirect benefits are related to wood's role as a roughness element, and this role is especially obvious in smaller streams where wood

can bridge much of a channel (Zalewski et al. 2003). Large wood within a small channel dissipates flow velocity, which reduces the energy fish expend as they move upstream (Zalewski et al. 2003). Bisson et al. (1987) state that sediment storage by large wood benefits fish primarily by buffering the stream network against rapid changes in sediment load that would degrade habitats, such as rapid sediment increases due to landslides. Wood also benefits fish by increasing habitat diversity. In seeking a path around large wood obstructions, water creates complex hydraulic patterns that carve pools and side channels, form falls, and enhance channel sinuosity, imposing numerous variations in a stream's hydrology and geomorphology. Another indirect benefit of instream large wood is its influences on the availability of prey for fish in the form of macroinvertebrates. Large wood provides habitat for invertebrates, which then supplies fish with a source of food (Bisson et al. 1987).

The direct benefits of instream large wood to fish are also important. Large pieces of instream wood provide fish with refuge from high velocity flows during floods and provide hiding cover from predators (Sedell et al. 1985; Bisson et al. 1987; Braun and Reynolds 2011). Uprturned tree roots and logs were the most common type of cover used by juvenile Coho Salmon and steelhead in an unlogged, west coast Vancouver Island stream (Bustard and Narver 1975). The deep pools often formed around these features made for good cover, particularly for older juveniles (Bustard and Narver 1975). After logging, almost all Coho Salmon that remained in channels over the winter sheltered in stream segments jammed with logs, with undercut banks, and in pools filled with upturned tree roots and other forest debris (Tschaplinski and Harman 1983). Hartman (1965) also found overwintering Coho Salmon fry preferring cover near logs, roots, and banks in streams in coastal British Columbia. Large wood increases fish density by visually isolating individual fish, which reduces inter- and intra-species competition (Dolloff and Reeves 1990; Crook and Robertson 1999).

### 3.5.2. Amphibians and Reptiles

Amphibians can be a dominant biotic component in Pacific Northwest streams (Olson et al. 2007), but in contrast to fishes and invertebrates, studies that characterize the importance of instream large wood for amphibians are sparse (Wondzell and Bisson 2003). However, diverse sources of data on stream-associated amphibian species life histories indicate that instream wood contributes to the creation and maintenance of breeding, rearing, and foraging habitats, and likely overwintering habitats as well. In particular, large wood can serve as the instream substrate for amphibian oviposition (Henry and Twitty 1940; Jones et al. 1990). Wood also forms steps in streams that promote sediment wedges (May and Gresswell 2003) that serve as variable but often extensive habitat matrices for oviposition and rearing (Nussbaum 1969; Wilkins and Peterson 2000). Moreover, wood-formed steps often create dam and plunge pools that are important for amphibian foraging or refuge (Wilkins and Peterson 2000; Welsh and Lind 2002). The basis of the former is that many aquatic invertebrates eaten by stream-associated amphibians occur in the habitat matrices created by wood-formed steps (Parker 1994; Steele and Brammer 2006; see next section). In coastal Washington headwater streams, the density of stream-associated amphibians

*Van Dyke's Salamander* *Plethodon vandykei* use large wood for cover/  
Eric Lund, WDFW

was positively correlated with the amount of functional large wood ( $R^2 = 0.50$ ), and torrent salamander (family Rhyacotritonidae) densities were positively correlated with the percentage of pools, indicating the importance of habitat complexity that large wood creates (Jackson et al. 2007). In Olympic National Park, large wood was a significant variable in explaining the densities of all three stream-associated amphibian species that were present, but its relative importance varied between species and was less important than one or more of aspect, gradient, and substrate in habitat use models for tailed frogs (family Ascaphidae) and torrent salamanders (Adams and Bury 2002).

Instream large wood is especially important for one Pacific Northwest reptile order: turtles. In the Northwest, water temperatures, even in the lowland stillwater habitats in which our two native turtle species occur, is often limiting (Holland 1994). Hence, the ability to bask securely (i.e., in a relatively predator-

free environment) at temperatures that exceed those of water is critical to the normal processes of digestion and for female turtles, successfully yolking up eggs. Large floating or anchored-downed logs with enough area extending above the water surface are the key structures on which basking can occur (Holland 1994). Such structures are especially important in stillwater side- and off-channel habitats of large streams.

### 3.5.3. Aquatic Invertebrates

The distribution and abundance of aquatic invertebrates are influenced by instream wood and certain taxa are dependent on instream wood. In streams of all sizes, areas of wood accumulation are often also invertebrate biodiversity hot spots (Benke and Wallace 2003; Wondzell and Bisson 2003). Many aquatic invertebrates use the numerous grooves, splits, and fissures in large wood as refuges from predators and harsh environments. Other invertebrate uses of wood include

*Large wood in Deschutes River/Noll Steinweg, WDFW*

oviposition, case making, and emergence, especially when submerged pieces are decayed rather than firm (Harmon et al. 1986). Several families of caddisfly use wood for case construction. Of ninety-two case-making caddisfly genera reviewed by Wiggins (1977), roughly a quarter exploit bark or wood to varying degrees for case construction. Instream wood also is used as sites for oviposition above and below the water line. Many caddisflies in the family Limnephilidae deposit their egg masses on moist wood. In the Coast Range of Oregon, Wisseman and Anderson (1984) found oviposition by a number of caddisfly taxa on overhanging logs. The surfaces of instream wood also are used as nursery areas for early instars, and for resting, molting, and pupation (Anderson et al. 1978).

Large wood is especially important as substrate for invertebrates to attach to in rivers with limited sources of stable substrate (Benke and Wallace 2003). Trees that have fallen into the main channels of low-gradient rivers frequently are the only stable habitat (Benke and Wallace 2003). In these streams, wood can be especially important for periphyton and macroinvertebrate taxa to attach themselves (Benke and Wallace 2003). In contrast to smaller rivers, instream large wood shifts to channel margins and floodplains of larger rivers (Bisson et al. 1987), and hence, in these main-stem locations invertebrate densities peak (Ward et al. 1982). In headwater streams, large wood and gravel habitats supported higher densities and biomass of benthic invertebrates than cobble habitats (Hernandez et al. 2005). Coe et al. (2009) saw significantly higher densities of invertebrates in Pacific Northwest streams where engineered logjams were added. They attributed this to increased overall habitat surface area, and thereby the potential for increased productivity relative to reaches with low levels of wood. Instream large wood also supported a richer and more diverse invertebrate fauna than either cobble or gravel substrates.

Wood provides invertebrates with access to a wide variety of food sources. Large wood traps and stores

*Large wood on Cedar River/Hal Beecher, WDFW*

organic matter, and wood can be directly consumed by some invertebrates (Benke and Wallace 2003). Trapped organic materials are food sources for bacteria, fungi, mollusks, insects, and crustaceans. Although only a small fraction of aquatic insect taxa exploit woody debris as a source of food (Harmon et al. 1986), direct wood consumption by aquatic invertebrates in the Pacific Northwest has been observed in some species of caddisfly, mayfly, beetles, and snails (Anderson et al. 1978; Dudley and Anderson 1982; Pereira and Anderson 1982; Pereira et al. 1982). Submerged large wood may also support surface films of micro-organisms (e.g., diatoms, bacteria, fungi) that efficiently take up instream nitrogen and form a food web base for aquatic invertebrates (Dudley and Anderson 1982; Johnson et al. 2003), that in turn support vertebrate species (Ashkenas et al. 2004). By moderating pulses of fine sediment (Entekin et al. 2009), instream large wood also acts to reduce the accumulation of sediment on algae (Richardson 2008), which is an important food to many macroinvertebrate taxa.

### 3.5.4. Fish and Wildlife Summary

The vital ecological role of instream wood has been known for at least 40 years (Swanson et al. 1976). Relationships between high quality salmonid habitats and instream large wood are well established (Bisson et al. 1987; Dollof and Warren 2003). Invertebrate taxa,

such as aquatic insects, are also known to rely on large wood as a habitat substrate and food source. Juvenile salmonids prey on aquatic insects. Amphibians and turtles also depend on the channel morphology and wood structure created by instream large wood.

## 3.6. Land Use Effects

**T**he major human land uses in Washington—urban/suburban, agriculture, and forestry—have altered or removed extensive areas of riparian forest and have adversely impacted instream wood size, abundance, and distribution, and left many streams with a chronic deficiency of instream large wood compared to historical conditions (Maser et al. 1988; Bilby and Ward 1991; Stouder et al. 1997; May et al. 1997).

In general, the three major land uses impact instream large wood in similar ways—they diminish the amount of instream wood by reducing the number and size of trees in riparian areas. Furthermore, large wood is often purposefully removed from rivers and streams because it can block culverts or damage other human-made structures such as bridges, dams, or levees; cause streambank erosion that destroys private property; and present hazards to navigation or recreation. Culverts and dams also disrupt the transport of wood through a stream network and reduce the amount of wood in higher order streams and rivers.

*Juvenile fish use large wood for shelter/WDFW*

Most research on instream wood and riparian forests has occurred in unmanaged and managed forests, but much of the knowledge gained in forests—such as the functions of instream wood, natural amounts of instream wood, and recruitment mechanisms—is applicable to riparian areas in urban/suburban and agricultural settings as well, especially in forested ecoregions.

### 3.6.1. Forestry

Because mature conifer trees in the Pacific Northwest have large-diameter, decay-resistant boles, streams in this region have naturally high volumes of large wood compared to other parts of North America (Harmon et al. 1986). Nevertheless, harvest in and around riparian areas can result in immediate and long-term changes to the volume of instream wood. Czarnomski et al. (2008) found that instream wood volume and abundance varied significantly relative to timber harvest and adjacent tree stand age. They found instream wood volume and abundance were significantly higher in streams adjacent to unmanaged, mature and old-growth stands compared to streams along 30- to 50-year-old plantations, and significantly less in streams adjacent to 30- to 50-year-old plantations compared to those adjacent to 20- to 30-year-old plantations or mature and old-growth forest. Beechie et al. (2000) estimated that if a riparian buffer was established today in a 50-year-old stand of Douglas-fir, recovery of pool-forming large wood might take less than 100 years in small channels (e.g.,  $\leq 66$  ft [20 m] wide), but could take as much as 200 years in larger channels.

The impacts of logging on instream large wood and aquatic habitats may not be realized for many decades after logging. In interior British Columbia, Chen et al. (2005) found that in the short term, instream large wood volume and biomass increased after logging. However, they concluded that in the long term, abundance of instream large wood may be greatly reduced as a

result of increased rates of decay, transport, and reduced recruitment from the adjacent riparian forest. With instream wood residence times averaging about 30 years, Hyatt and Naiman (2001) estimated that harvesting large riparian conifers would adversely impact aquatic habitats of large streams in about three to five decades. Murphy and Koski (1989) showed a 70% reduction of instream large wood 90 years after clearcutting without a riparian buffer. They also estimated a 250-year recovery time to pre-harvest levels.

*Harvest near riparian areas can impact aquatic habitats/Marc Hayes, WDFW*

The loss of riparian trees can come with long-term repercussions to functional aquatic habitat. Where riparian trees are absent, Beechie et al. (2000) predicted a lag of 7-49 and 15-91 years before pool-forming large wood could be recruited from Red Alder and Douglas-fir forests, respectively. The lag time for a given stream depends on multiple factors including channel width and the minimum size of pool-forming wood. In Alberta, instream large wood generated from stand-replacing fires was depleted within 100 years of the event but once the forests reestablished, new large wood recruitment was delayed by roughly 40 years (Powell et al. 2009).

A riparian management zone (RMZ) adjacent to logging differs in its ability to supply instream wood compared to riparian areas adjacent to unlogged uplands. On average, tree mortality was 50% greater in RMZs compared to riparian areas in unlogged landscapes, 3 to 15 years post-harvest (Martin and Grotefendt 2007). Differences in stand mortality between logged and unlogged tracts were primarily due to greater windthrow at a small proportion of RMZs in logged tracts. Additionally, downed tree recruitment from RMZ outer zones was more than double that of trees recruited

in unlogged tracts. Consequently, wood recruitment increased by an average of 2 trees per 330 ft (100 m) in the buffered versus unlogged forested tracts (Martin and Grotefendt 2007).

Trees in RMZs with adjacent clear-cuts may be more susceptible to windthrow. Windthrow in RMZs (85 ft [26 m] wide on both side of streams) increased instream large wood by 34% within one to three years after logging in small streams (Grizzel and Wolff 1998). The authors of that study suggested that the RMZs adjacent to clearcuts served as a long-term source of large wood. They added that over a 10-year period, windthrow could add an average of 1.9 trees per 984 ft (300 m) of stream. Along second to fifth order streams, windthrow in RMZs was 26 times greater up to three years post-harvest compared to estimated mortality rates of trees in riparian stands in unlogged tracts (Liquori 2006). Post-harvest windthrow may reduce tree density in RMZs enough to significantly reduce competition-induced tree mortality, which in turn may lead to substantially different wood recruitment dynamics in buffers compared to unlogged forests (Liquori 2006).

### 3.6.2. Urban/Suburban

Very few studies have examined the impacts of development on instream large wood dynamics. In their analysis of the effects of urbanization, May et al. (1997) noted that as a basin's urbanization increased the quantity of large wood declined, as did related measures of habitat quality, namely loss of riparian forest area, reduced pool area, and decreased habitat complexity. Urban streams greater than 2% gradient and lacking large wood were found to be more susceptible to scour than less developed counterparts. Other than restoration sites where instream large wood had been replaced, high quantities of instream large wood were only found in undeveloped watersheds.

An analysis of relationships of channel characteristics, land ownership, land use, and land cover to instream large wood abundance in western Oregon showed that the most important predictor for large wood volume was land ownership, followed by stream gradient (Wing and Skaugset 2002). They also observed fewer large wood pieces in streams near rural residential areas compared to managed forests. In a study outside the Pacific Northwest, researchers in the Piedmont region of Georgia found that the absence of forest cover in catchments in suburban Atlanta corresponded to a decrease of instream large wood biomass (Roy et al. 2005).

*Agricultural area in western Washington/Marlin Greene, One Earth Images*

### 3.6.3. Agriculture

Many types of agriculture remove riparian forest, and consequently, reduce the recruitment of large wood to fish-bearing rivers and streams. Within the Nooksack River basin of northwest Washington, riparian forest along reaches accessible to anadromous fish were evaluated based on their ability to contribute instream wood large enough to form pools (Hyatt et al. 2004). Seventy-four percent of this basin's riparian forests that failed to meet this criterion were found in lowland rural-agricultural areas. In contrast, only 20% of the stands that failed to meet this threshold were in federal and commercial forestlands. This contrast is notable given that agricultural and rural areas comprised only about 22% of Nooksack basin (Hyatt et al. 2004). Similar results were observed in an analysis relating land use and land cover to instream wood abundance in western Oregon (Wing and Skaugset 2002). In this study, they found fewer pieces of large wood in streams near agricultural land uses compared to that of managed forestlands.

In shrub-steppe and grassland ecoregions of eastern Washington, livestock grazing in riparian areas significantly reduces the amount of woody vegetation. Significant reductions in woody vegetation lead to numerous adverse impacts to aquatic habitats: increased streambank erosion, increased overland flow and erosion within riparian areas, increased turbidity, reduced shade, higher water temperatures, loss of cover for fish due to reductions in overhanging vegetation and undercut banks, reduction in the amount of instream small wood, changes to channel morphology such as fewer pools, fewer meanders, and channel incision, lowering the water table, and reduction in essential nutrients derived from detritus (Belsky et al. 1999).

### 3.6.4. Land Use Effects Summary

Land uses that affect riparian forest also affect instream large wood. Of the three major land uses, contemporary forestry has the least effect on instream large wood. However, for all three land uses, the severity of effects depends largely on how riparian areas are managed.

## 3.7. Conclusions

**M**any effects of wood on aquatic ecosystems are well understood and not subtle, and therefore, ecologists are very confident about the critical role of wood in fish habitats. Ecologists are also confident about the role of riparian forests in supplying large wood to aquatic systems. Successful conservation of fish habitats and fish species in the forested regions of Washington depends on riparian forest management that delivers adequate wood to aquatic ecosystems. From a management perspective, the main scientific uncertainties are: 1) the shape of the wood recruitment function (e.g., Figure 3.5), especially the shape under different watershed and site-level conditions; and 2) the potential contributions from recruitment mechanisms outside the riparian forest, such as landslides, debris flows, or extreme channel migration. Addressing these uncertainties through research could lead to more ecologically effective and economically efficient management of riparian areas.

To maintain or restore 100% of a site's large wood recruitment potential, the site's composition and structure should be similar to that of an unmanaged riparian forest. Given current uncertainties, re-establishing riparian forest similar to unmanaged, mature or old-growth forests should be the most reliable way to provide instream large wood sizes and abundance that are similar to historical levels.

An important management question is: what are source distances for large wood recruitment from riparian areas to aquatic ecosystems? We know that source distances for wood in riparian areas are a function of tree height—source distances are longer for riparian forests with taller trees. We also know that tree heights for old-growth conifer forests can exceed 200 ft (60 m). In Washington State, Fox (2003) found that mean heights of canopy trees in old-growth riparian areas (i.e., stand age > 200 years old) ranged from 100 to 240 ft (30 to 73 m). Height variation among riparian areas was largely explained by forest zone and site productivity class. If large wood has a minimum diameter of 4 in (10 cm), then only that portion of a tree's stem greater than 4 in (10 cm) in diameter is large wood. From tree taper equations for Douglas-fir (Biging 1984), we know that for trees between 100 to 240 ft (30 and 73 m) tall about 15 to 3 percent of the stem is not large wood, respectively.<sup>3</sup> In other words, for the purpose of large wood recruitment, the "effective" tree height (*sensu* Robison and Beschta 1990; Van Sickle and Gregory 1990) ranges from 85 to 230 ft (26 to 70 m), depending on site productivity class. Therefore, in forested ecoregions, 100% of a site's large wood recruitment potential, is located about 85 to 230 ft (26 to 70 m) from the stream channel, depending on site productivity class. These source distances only account for trees recruited via bank erosion, windthrow, or tree mortality. It does not account for large wood recruited to the stream channel through landslides or debris flows, nor does it account for recruitment through extreme channel migration in large river floodplains. In addition, this does not account for source distances of small wood. Source distances for small wood equal a full tree height from the stream channel.

---

*Ecologists are confident about the critical role of wood in creating fish habitat and the role of riparian forests in supplying large wood to aquatic systems.*

<sup>3</sup> Effective tree height calculations were done in Microsoft Excel with equations from Robison and Beschta (1990) and Biging (1984).

# Chapter 4. Stream Temperature

By: Kirk L. Krueger, Daniel J. Isaak, and Marc P. Hayes

## 4.1. Introduction

**T**he great diversity of Washington's landscapes creates equally diverse stream thermal conditions (Figure 4.1). Broad ranges in elevation (0 - 14,000 ft, 0 - 4,300 m), precipitation, stream size, topography, and other factors contribute to some streams having average summer temperatures as low as 39°F (4°C); whereas others only a few miles away may exceed 68°F (20°C). Much of that thermal heterogeneity is dictated by effectively immutable geomorphic attributes of landscapes (e.g., elevation, aspect, topographic slope), which affect the potential amount of solar radiation available at a given location (Boyd and Kasper 2003). However, the types of riparian

vegetation and their condition also play important roles in determining the amount of solar radiation that reaches a stream's surface. Through management of riparian ecosystem conditions, especially vegetation, the spatiotemporal distribution of stream temperatures (i.e., thermal regime) (Boyd and Kasper 2003; Caissie 2006) can be affected, which in turn, directly and indirectly affect the survival and productivity of aquatic species (Beschta et al. 1987; McCullough 1999) including salmon.

Shade can substantially reduce the amount of direct (shortwave) solar radiation, usually the main cause of heating, that reaches a stream (Poole and Berman 2001). Indirect effects of riparian vegetation include, but are not limited to, maintenance of channel form and

*Pink Salmon Oncorhynchus gorbuscha moving upstream to spawn/Ned Pittman, WDFW*

hyporheic connectivity (Gregory et al. 1991; Stanford 1998; Poole and Berman 2001) that also affect stream temperatures (Boyd and Kasper 2003; Webb et al. 2008). Maintaining and restoring riparian ecosystem functions and the thermal regimes of aquatic systems is increasingly important in light of climate change and as land use intensifies. Land use can strongly influence the intensity, timing, duration, and geographic distributions (i.e., structure) of stream temperatures (NRC 2002).

In this chapter we briefly summarize the results of our literature review, and present a simple conceptual model that identifies components (environmental factors) and structures (relations of components) that affect stream temperatures, to facilitate understanding of potential effects of different management alternatives. We also briefly discuss considerations of the effects of riparian management on stream thermal regime within a watershed or stream network context, the sensitivity of some priority species to changes in stream thermal regime, and applications of current scientific information to riparian management for suitable thermal regimes for aquatic species. Much of the literature describing the effects of human activity on stream temperature has focused on summer maximum water temperatures. Increasingly, scientists are focusing on better understanding stream thermal regimes, which describe how the temperature of streams varies through time and throughout stream networks. This shift recognizes two important ideas: 1) fish and other aquatic organism use different stream habitats, defined in part by specific water temperature ranges, to complete their life cycle, and 2) heat energy inputs into streams are variable in space and time and heat energy is often carried downstream of the reach from which it was gained.

Our review of the scientific literature on the effects of riparian conditions on stream temperatures was extensive; including more than 6,000 articles relevant to riparian ecosystem research, of which more than 700 referenced stream temperatures and over 100 that referred to or reported measured effects of riparian

ecosystem conditions on stream temperatures. Our work also identifies research to inform management recommendations that are applicable across a wide range of environmental conditions (e.g., various latitudes, topographies, and land uses). Further, we wanted to address the broad range of thermal conditions that are important to aquatic species (e.g., frequency, duration, intensity, and predictability of summer high temperatures and temperatures during incubation (Lytle and Poff 2004); and the geographic distribution of stream temperatures (Torgersen et al. 1999; Poole et al. 2001; Ebersole et al. 2003a). Therefore, we reference additional scientific information to provide the context that allows for better understanding and application of riparian ecosystem-specific information. Several reviews were particularly valuable in directing our efforts (e.g., Elmore and Kauffman 1994; May 2003; Moore et al. 2005; Sather and May 2007; Bowler et al. 2012; Czarnomski and Hale 2013).

*Scientists are focusing on better understanding stream thermal regimes, which describe how the temperature of streams varies through time and throughout stream networks.*

Figure 4.1. Stream thermalscape showing mean August temperatures for 66,236 kilometers (41,157 miles) of streams across Washington that was developed in the NorWeST project (poster available here: [http://www.fs.fed.us/rm/boise/AWAE/projects/stream\\_temp/downloads/14NorWeST\\_WashingtonStreamTemperatureMap.pdf](http://www.fs.fed.us/rm/boise/AWAE/projects/stream_temp/downloads/14NorWeST_WashingtonStreamTemperatureMap.pdf)). Topographic and geomorphic complexity across the state creates significant thermal heterogeneity that is moderated locally by riparian conditions.

### 4.1.1. State of the Science

The scientific literature establishes a clear expectation that reduction of stream shade, especially due to vegetation removal, will result in warmer summer stream temperatures (e.g., Sridhar et al. 2004; Allen et al. 2007). The literature, derived primarily from descriptive (e.g., case study) and occasionally statistically predictive (e.g., generalization across many case studies) studies, demonstrates that riparian management can affect shade and in turn stream temperatures (Johnson 2004; Moore et al. 2005). The vast majority of those studies document an increase in a temperature statistic, often mean daily maximum temperature during summer, associated with a loss

of shade (Johnson 2004; Moore et al. 2005; Bowler et al. 2012), but a few studies have shown mixed results (Johnson 2004; Moore et al. 2005; Janisch et al. 2012; Kibler et al. 2013).

Variability in stream temperatures among locations (Figure 4.1) and among some study results is due to both temporally constant attributes of landscapes (e.g., elevation, topographic slope, drainage area) and temporally variable attributes (e.g., stream wetted width, stream flow) that affect the potential amount of solar radiation available at a given location (Boyd and Kasper 2003) and the thermal sensitivity of the stream, respectively. The amount of solar radiation available is often referred to as thermal loading potential or

potential solar load. At a given thermal input or load, the temperature change responsiveness of a stream is often referred to as “thermal sensitivity” (Beschta et al. 1987; Moore et al. 2005). Thermal sensitivity is influenced by many physical factors. Streams with higher flows of surface and groundwater, and hyporheic exchange rates (Cristea and Burges 2010; Arismendi et al. 2012) tend to be relatively thermally insensitive. Wood loading, channel complexity and depth can also affect thermal load and sensitivity. The potential solar load in combination with thermal sensitivity (discussed in detail below) of locations across a stream network and through time largely determine a stream thermal regime.

In addition to solar radiation, other microclimate variables - such as air temperature, wind speed, and humidity - may affect instream water temperatures. Microclimate conditions interact with energy exchanges at the air-water interface (Figure 4.2) and can thereby affect stream thermal regimes (Moore et al. 2005; Benyahya et al. 2010), especially in small streams (Caissie 2016). However, we believe the effects of microclimate on the thermal regime of streams with fully functioning riparian ecosystems are minor for two reasons: 1) microclimate effects (e.g., changes in air temperature and humidity) at forest edges rarely extend farther than one tree height into mature riparian forest (Moore et al. 2005; Rykken et al. 2007; Reeves et al. 2018), and 2) sensible heat exchanges comprise only a small portion of total heat flux in streams (Johnson 2004; Moore et al. 2005). In fact, net solar radiation effects on stream temperatures are generally about an order of magnitude greater than sensible and latent heat exchanges at the air-water interface (Moore et al. 2005; D. Caissie, Fisheries and Oceans Canada, personal communication). However, we also agree with Reeves et al. (2018), who note that the range of effects measured in different studies suggests substantial uncertainties regarding riparian ecosystem management with respect to microclimate.

Riparian ecosystem-stream temperature research appears to be transitioning from largely local, descriptive (e.g., case study and generalizations of case studies) to predictive, mechanistic, and deterministic modeling across larger areas (e.g., Boyd and Kasper 2003; Allen et al. 2007). Mechanistic models attempt to include most of the factors that affect stream temperatures (Figure 4.2) in a given area and thus do not rely on statistical extrapolation from other locations. These types of models can provide relatively accurate and precise temperature predictions at various spatial and temporal scales (Leinenbach et al. 2013). Further, they can provide useful information on systems and processes that are not readily estimated through statistical approaches used in case studies. However, collecting the environmental data necessary for accurate prediction of the effects of riparian management actions on stream thermal regimes via mechanistic models is difficult and often prohibitively expensive (Allen et al. 2007). For example, studies on the effects of riparian ecosystem or land cover management on stream temperatures at large spatial extents (e.g., watersheds of large streams or rivers) and cumulative effects are very rare. Watershed-scale studies (e.g., Janisch et al. 2012; Kibler et al. 2013) are often limited to relatively small watersheds (e.g., 2 to 1,000 ha) and second order streams.

New types of statistical models for stream network data (Ver Hoef et al. 2006; Isaak et al. 2014) have been applied to large stream temperature databases (Isaak et al. 2017a) and these have enabled relatively accurate predictions ( $R^2 = 0.90$ ; RMSE = 1.8°F or 1.0°C) and mapping of summer thermal conditions across all Washington streams (Figure 4.1). Those statistical approaches use predictor variables derived from broad geospatial and remotely sensed datasets (e.g., elevation, stream slope, riparian density from the National Land Cover Database) so they do not provide insights to local temperature anomalies that could be associated with alterations of riparian or channel conditions. However,

these statistical models do provide accurate thermal status maps that could be used with mechanistic models or field measurements to better ascertain the influence of riparian conditions on stream temperatures.

Scientific knowledge of the importance of stream temperatures on aquatic species has also advanced since the publication of Knutson and Naef in 1997; especially by better describing the importance of thermal regimes (rather than only extreme high temperatures) on fish survival, growth, and productivity (Ward and Stanford 1982; McCullough 1999; Caissie 2006; McCullough et al. 2009; Hinch et al. 2012). For example, the collapse of the Fraser River Sockeye Salmon *Oncorhynchus nerka* spawning run in 2009 was largely attributed to thermal exposure due to early migration, which resulted in indirect, but often fatal, effects (Hinch et al. 2012). Following Olden and Naiman (2010), we suggest that thermal regimes can be described by their rates of change, magnitude, frequency, timing, and duration, and also their spatial distribution in a stream. The timing and duration of thermal exposure, in addition to exposure to extreme temperatures, affects the survival and productivity of many aquatic species (Caissie 2006).

Importantly, studies such as those of Murphy and Hall (1981), Murphy et al. (1981), Hawkins et al. (1983), and Bilby and Bisson (1987) that demonstrated apparent beneficial effects of reduced riparian shade on an aquatic species, such as increased salmonid growth or abundance, can now be considered in a broader ecological context. It should be noted that in these studies observed temperature increases were small and apparent beneficial effects were attributed to increased solar radiation, primary production, and consequent bottom-up stimulation of the food web. These findings are consistent with the idea that oftentimes the biological effects of altered temperatures differ among locations (Li et al. 1994; Farrell et al. 2008), and that such differences in effects may be attributed to the difference between local temperature and the

thermal niche of a species. For example, in reaches where temperatures are near a species' thermal maxima, additional warming will cause the habitat to become unsuitable. However, in streams that are too cold for a species, warmer temperatures may increase habitat suitability (Isaak and Hubert 2004; Isaak et al. 2017b). In addition to direct stream temperature changes on a single species, changes may affect ecological trade-offs between species. Rezende et al. (2014) showed that faster growth might also be associated with increased competition with non-native species (Lawrence et al. 2014).

Widespread alterations of upland and riparian conditions and subsequent changes in stream composition and structure have likely already impacted thermal conditions in many streams (Poole and Berman 2001) and such impacts will be further exacerbated by the ongoing effects of climate change (Isaak et al. 2012; Holsinger et al. 2014). Streams with degraded riparian conditions, however, also offer opportunities where restoration actions could mitigate future warming and improve ecological resilience by enhancing the survival and productivity of the populations and assemblages that use those systems.

## 4.2. Conceptual Model

**W**e provide a conceptual model to help describe the important components, structures, and processes that affect stream temperatures and that can result in different effects of riparian management actions on stream temperatures among locations (Figure 4.2). Our conceptual model is largely a simplification of the model "Heat Source" in Boyd (1996) and Boyd and Kasper (2003) and developed based on the preponderance of scientific evidence. Heat Source is a deterministic, mechanistic model developed to predict dynamic open channel heat and mass transfer. As such, it includes parameters for all variables that are known

to significantly affect stream temperatures. Our simplified conceptual model describes components and parameters that can have a large effect on stream temperatures or that are affected by riparian ecosystem management. We provide this model in an attempt to improve basic understanding of stream thermal processes and to identify important composition, structure, and functions that are subject to management and that affect stream temperatures. Additional information based on the models of Poole and Berman (2001), Moore et al. (2005), and Leinenbach et al. (2013) are included to more clearly identify factors that affect thermal loading potential and stream thermal sensitivity via riparian management.

Scientific understanding of the environmental factors and their relations that affect stream thermal regimes is well developed, as demonstrated by the development of deterministic, mechanistic models (e.g., Boyd and Kasper 2003) that can provide accurate temperature predictions when sufficient data are available to run the model and when the stream system remains relatively stable. Such models have been applied successfully at the spatial extent of individual stream reaches (Cristea and Janisch 2007; Cole and Newton 2013) and watersheds (Coffin et al. 2011; Bisson et al. 2013; Booth et al. 2014), suggesting that our understanding of the composition, structure, and functions that affect stream temperatures are well understood and can be

Figure 4.2. Conceptual model that identifies some factors that affect the thermal regime of stream networks. Relative importance is noted by line weight and arrows indicate directions of flows. Note that most of the elements in the model are influenced by human activities and that many components and structures are not presented here. See Boyd and Kasper (2003) for a more thorough review.

*Dense tree canopies rarely provide 100% shade/Ned Pittman, WDFW*

reliably applied to management problems. Rates of direct (shortwave) solar radiation reaching the stream surface and the volumes and temperatures of water are consistently identified as the dominant processes affecting the thermal regime of streams (Sinokrot and Stefan 1993; Johnson 2004). At many locations these two dominant processes are subject to management: direct solar radiation reaching a stream via vegetation management and water flows via water diversion, storage, and return (Olden and Naiman 2010).

The thermal loading potential of a stream reach is controlled in part by temporally constant and largely independent factors such as latitude, aspect, elevation, and topographic shading (Figure 4.2, Boyd and Kasper 2003; Janisch et al. 2012). Streams at high latitudes are less exposed to solar radiation, the ultimate source of heat energy to streams, than streams at low latitudes. Stream aspect affects stream temperatures because a stream's orientation relative to the path of the sun (which differs seasonally) determines the amount of direct solar radiation that a stream receives (Johnson 1971). Elevation affects the ambient air temperatures that streams are exposed to, as well as the dominant form and amount of precipitation (i.e., snow or rain). For these reasons, higher elevation streams are usually colder and commonly, although not always, less thermally sensitive than lower elevation streams (Luce et al. 2014). Topography can shade a stream from direct solar radiation and the effects of topography and aspect

can interact. The effects of these four geographic factors can be difficult to detect (Isaak and Hubert 2001) and are likely responsible for some of the variability of the results of case studies that measured the effects of riparian management on stream temperatures. Note that some of these attributes (e.g., elevation) also affect the composition and structure of riparian vegetation. Stream thermal loading is not only controlled by independent factors such as latitude, aspect, elevation, and topographic shading. The scientific literature clearly identifies shade from riparian vegetation as important to stream temperatures, especially for small (narrow) streams (e.g., Beschta 1987; Poole and Berman 2001; Johnson 2004; Sridhar et al. 2004; Moore et al. 2005; Caissie 2006; Allen et al. 2007; Bowler et al. 2012; Garner et al. 2014). The effects of altered stream shading on temperatures is complex because thermal loading potential and thermal sensitivity of streams differ among locations. Some attributes, such as water volume, wetted width, and width-depth ratio can affect both thermal loading potential and thermal sensitivity (Cristea and Janisch 2007; DeWalle 2010). For a given volume of water, wider channels of the same length have a greater surface area that can intercept more direct solar radiation (Boyd and Kasper 2003) and also exchange more heat through atmospheric conduction. The width of a stream also affects the amount of shade that can be provided by topography and riparian vegetation (Cristea and Janisch 2007; DeWalle 2010). That is, riparian vegetation of given height, density, and width might shade a larger proportion of a narrow channel for a longer period than for a wide channel. Stream widths, especially wetted channel widths, are often much less temporally stable than the other factors that control thermal loading potential. Management actions that result in changes in stream width (e.g., over-grazing [Belsky et al. 1999; Chapter 2] and maintenance of wide forested riparian areas that can result in wide channels [Sweeney and Newbold 2014]) can increase thermal loading potential and thermal sensitivity.

While shortwave radiation input and water volume and temperature largely control temperature regime, longitudinal channel form (stream reach and cross section) can also affect stream temperature, for example, via high sinuosity and the presence of undercut banks (Frissell et al. 1986; Bisson et al. 2006). Channel form and features that increase stream roughness can store gravel (Buffington et al. 2004) and increase hyporheic exchange (Wondzell and Gooseff 2013) that, in turn, can affect stream temperatures by storing and releasing heat (Burkholder et al. 2008). Large wood can also store large amounts of gravel in some streams (Buffington et al. 2004) and affect channel form (Chapter 3; Keller and Swanson 1979; Abbe and Montgomery 1996; Konrad et al. 2005) which might subsequently affect stream temperatures. For example, sediment deposition due to instream large wood might increase hyporheic flow and stream width, which can subsequently effect stream temperatures. Steep or undercut banks can also provide shade (Boyd and Kasper 2003) which, in some locations (Ebersole et al. 2003b), can lower water temperatures at small spatial extents (e.g., individual pools; Ebersole et al. 2003a), even in large streams and rivers. Unfortunately, relatively few studies quantify the effects of channel form on thermal sensitivity and stream temperatures, which likely adds variability among stream temperature case studies and limits our ability to predict their relative importance at specific locations. Groundwater and tributary flows also affect stream temperatures (Malard et al. 2002) in two ways, 1) by adding volume and increasing flow velocity that can make streams less sensitive to thermal change (i.e., increasing thermal capacity), and 2) by adding water that is at a different temperature than receiving waters (Boyd and Kasper 2003; Story et al. 2003). However, the effects of groundwater flows can be difficult to detect due to spatiotemporal lags (Alvarez et al. 2004; Arrigoni et al. 2008) and difficult to apply to management due to the paucity of information describing groundwater flows. Additionally, side channels and wetlands can provide large volumes of water at different temperatures to

receiving stream water (Bobba et al. 2010). Streambed attributes, such as porosity and surface area, are largely controlled by the flows of water and available sediment (see Chapter 2). Streambed attributes can affect the thermal regime of a reach by affecting heat conduction (Sinokrot and Stefan 1993), by regulating the amount and velocity of water flow through the streambed, and by controlling the rates and locations of groundwater flows (Malcolm et al. 2002). The effects of these processes on stream temperatures can be spatially and temporally discontinuous and dynamic, especially in systems where stream form is heterogeneous and dynamic (Wright et al. 2005; Wondzell 2012). Hyporheic flows often have little effect on average stream surface water temperatures except for small streams at low flows but can create discrete locations of cool water (Wondzell 2012) that may serve as important refugia for salmon. Hyporheic flows can be influenced by flow regulation (e.g., dams), which can reduce variation in both flows and temperatures that reduces the potential for hyporheic exchange to act as a thermal buffer (Ward and Stanford 1995; Poole and Berman 2001; Nyberg et al. 2008).

*Juvenile salmon/Portia Leigh, WDFW*

The interaction of complex in- and near-stream riparian ecosystem processes can lead to a cascade of events (i.e., a series of related events triggered by single event) and new system states (Pringle and Triska 2000; Allan 2004). These cascading events are almost impossible to predict. For example, the removal of riparian trees typically reduces shading and increases solar radiation to the stream. Even when reductions in shade have a small direct effect on stream temperatures, the loss of trees can increase bank susceptibility to erosion (Chapters 2 and 3; Micheli and Kirchner 2002; Gomi et al. 2004) resulting in a wider stream that increases thermal loading and thermally sensitivity of the stream. Similarly, channel incision resulting from riparian management, may increase local topographic shading to the stream, but lower streambed and water elevations that can shift the riparian vegetation composition and structure. This shift in riparian vegetation can result in less stable streambanks and less riparian shade that ultimately offsets any benefits of topographical shading on water temperature (Toledo and Kauffman 2001). The results of such interactions are difficult to predict because they rely on accurate predictions of changes to stream morphology, vegetation composition and structure (which interact and have non-linear responses), and water and sediment flows (which can be stochastic).

The processes that affect the timing, duration, and geographic distribution of stream temperatures are complex due to the variability of the environment in which these processes occur (Figure 4.2). The relative importance of these ecological processes differs among locations and through time (Poole and Berman 2001; Webb et al. 2008). Scientific literature is clear about the expected effect of reducing stream shading, especially during summer; water gets warmer, particularly peak temperatures. Science is less able to provide accurate and precise predictions of the effects of specific riparian management measures. For example, the studies presented in Figure 4.3 represent statistical models

relating changes in riparian buffer width to changes in stream temperature. Data in Figure 4.3 are collected by measuring stream temperature before and after a reduction in the width of a forested riparian buffer which in turn decreases shade to the stream. Model output (prediction) is change in temperature related to specific buffer widths. The models tell us that reducing shade usually increases stream temperatures (following the shape of the dotted line connecting points), but they cannot predict exactly how much shade reduction will result in a specific temperature increase. A manager attempting to use the statistical model in Figure 4.3 to predict how a reduction from a fully forested site to a 30-foot wide buffer might affect summer stream temperatures is confronted with a range of possible answers. Those answers fall within the 90% credible intervals for one study representing a change between 1.25 and 2.25°C (2.25 and 4.05°F), and for another study between -0.5 to nearly 5.0°C (-0.9 to nearly 9.0°F). Uncertainty in this case describes our inability to accurately predict exact outcomes. While rarely applied due to their expense, mechanistic models and attendant data (e.g., hyporheic flows and temperatures) provide the best approach for predicting accurate site-specific outcomes from management.

Fortunately, the literature is very clear that solar radiation is often the dominant factor affecting stream heat budgets during all seasons except winter (Webb et al. 2008). Results of case studies can prove very useful by clearly describing the expected direction and shape of the relations between attributes of riparian ecosystems (e.g., width of vegetation) and stream shade and temperature. Importantly, riparian shade is often directly amenable to management and in many locations riparian vegetation height and density may be more closely associated with shade than width of riparian vegetation per se (DeWalle 2010). In any case, the literature is very clear about the importance of riparian vegetation for providing shade to streams (Figure 4.3a).

## 4.3. Species Sensitivity

### 4.3.1. Fish

**T**he scientific literature describing the importance of temperature, especially high temperatures, to fish is extensive (e.g., Brett 1952, 1971; Brett et al. 1969; Richter and Kolmes 2005). As aquatic ectotherms, the physiology of fish are strongly affected by water temperatures (McCullough et al. 2001; Welsh et al. 2001). Studies have frequently found associations between temperature and the geographic distribution (Welsh et al. 2001), spawn timing (Hodgson and Quinn 2002), growth rates, egg development and survival, competitive interactions, life stage survival, and behavior of fish (McCullough 1999; McCullough et al. 2009). Salmonids have frequently been studied because of their cultural and economic importance and their relative sensitivity to

high temperatures, narrow thermal tolerance, and narrow aerobic scope (Farrell et al. 2008; Eliason et al. 2011; Ayllon et al. 2013). Summer temperature information is useful for identifying acute problems, but may be insufficient for ensuring population resilience because indirect effects and exposure to altered thermal regimes, not just extreme summer temperatures, can affect fish survival and productivity (McCullough 1999).

Recent research has increasingly focused on the effects of water temperatures and thermal regimes for fishes that have narrow thermal tolerance (i.e., range of suitable temperatures) or aerobic scope (Farrell et al. 2008; Eliason et al. 2011; Ayllon et al. 2013). This work is particularly relevant to salmonids in the Pacific Northwest that have life histories adapted to historical, location-specific thermal regimes (Brannon et al. 2004; Farrell et al. 2008; Eliason et al. 2011). Much of this research is related to the increasing threats posed by climate change, and some studies have already found evidence of existing, detrimental effects of increased stream temperatures on fish. For example, Isaak et al.

*Juvenile anadromous salmon can spend up to 3 years in streams depending on the species/Ned Pittman, WDFW*

Figure 4.3. Observed shade (a: top panel) and temperature response (b: bottom panel) associated with “no-cut” riparian buffers with adjacent clearcut harvest. Only studies that employed a Before-After-Control-Impact design and conducted in Pacific Northwest forests are included. Shade unit is percent from completely shaded. Bayesian modeling results (and 90% credible intervals) were derived from data collected as part of Groom et al. (2011). Analyses provided by P. Leinenbach, USEPA Region 10.

(2010, 2015) found increases in stream temperatures would result in losses of Bull Trout *Salvelinus confluentus* and Cutthroat Trout *Oncorhynchus clarkii* habitats, but also that especially cold streams could serve as climate refugia during the 21st century. Additionally, a number of recent studies have described some complex effects of altered thermal regimes to the productivity and survival of fish at different life stages and dramatic differences in thermal tolerance and aerobic scope among populations and species. For example, Hinch et al. (2012) describe complex links between the physiology, behavior, environment, disease exposure, and the effect of thermal exposure, on the population-specific survival of migrating Sockeye Salmon. Hodgson and Quinn (2002), Keefer et al. (2007), Strange (2010) and others have documented that high temperatures and previous thermal exposure can inhibit fish migration, and Marsh (1985) and Kappenman et al. (2013) have documented that high and low temperatures can impede spawning and embryo development and that optimal temperatures for embryo survival and development differ among species. Steel et al. (2012) found that thermal variability (without changing mean temperature) can affect the emergence timing and development of Chinook Salmon *Oncorhynchus tshawytscha*.

The literature is conclusive about the importance of stream thermal regimes to fish survival and productivity and also demonstrates wide variability in sensitivity to altered thermal regimes among species and among populations within species (Steel et al. 2012). More research would help us fill the sizeable gap in our understanding of the risk posed by altered thermal regimes on the survival and productivity of populations of salmonids or non-salmonid fishes, and on the ecological interactions that affect survival, productivity and population viability. For example,

*Chum Salmon Oncorhynchus keta in spawning colors/Ned Pittman, WDFW*

the time of hatching (i.e., duration of incubation) of salmonid eggs is largely determined by their thermal exposure during incubation. Relatively small changes in temperature can advance or delay maturation and subsequently hatching date (Groot and Margolis 2010) and effects of temperature can differ among closely related populations of the same species that spawn in different habitats (Hendry et al. 1998). Regardless of the ultimate cause, changes in thermal regimes can, for example, uncouple trophic interactions due to temporal mismatches, such as fry emerging when their preferred food is not available to them (Winder and Schindler 2004; Post et al. 2008). Altered thermal regimes can also affect other life stages by altering the timing of parr-smolt transformation (Zaugg and Wagner 1973), the duration of freshwater rearing (Sauter et al. 2001) which can affect ocean survival (Weitkamp et al. 2015), and the timing and success of spawning migration (Crossin et al. 2008). Altered thermal regimes can also affect ecological interactions. For example,

---

*Wise management of riparian and aquatic systems would ideally consider the distribution and dynamics of stream temperatures in space and time and at scales that are relevant to the species in the region.*

Lawrence et al. (2014) demonstrated that higher stream temperatures can expand the geographic distribution of non-native Smallmouth Bass *Micropterus dolomieu* and increase their predation on salmon. These results are complicated by the fact that effects of altered thermal regimes often differ among populations and life stages of a species, and among species (Brett 1971; Zaugg and Wagner 1973) which makes prediction of the exact effects of any riparian shade reduction and subsequent effects on stream thermal regime on fish survival and productivity uncertain. This uncertainty is compounded by fish behavioral responses, such as daily and seasonal movement among locations where thermal conditions differ (Torgersen et al. 2001).

Our understanding of the importance of altered thermal regimes on fish has improved substantially since the publication of Knutson and Naef (1997). Discussion of stream temperature by Knutson and Naef (1997) focused mostly on summer high temperatures and their effects on fish, but did not identify many components and structures of ecosystems that can affect stream temperatures or the importance of thermal regimes to fish. In particular, more recent studies are able to measure thermal exposure of fish through time, occasionally in field conditions, and estimate physiological attributes such as growth rate (Sauter and Connolly 2010).

Most studies calculate a single statistic that describes an important attribute of a stream's thermal regime (e.g., mean maximum daily summer temperature) and identify species, population, or life stage attributes that are correlated with that statistic, such as a critical thermal limit. These studies have been useful for demonstrating the importance of temperature and for setting some management objectives. However, they are insufficient for effective, long-term management of perturbed systems because changes in temperature means (i.e., chronic exposure) or extremes (i.e., acute exposure) can result in different selective pressures and evolutionary responses (Rezende et al. 2014) and

because life stages, populations, and species differ widely in their sensitivity to altered thermal regimes (Farrell et al. 2008; Hinch et al. 2012). Further, we now better understand that many individual fish and especially populations use (and perhaps are dependent on) a dynamic mosaic of habitats (Fausch et al. 2002; Ward et al. 2002; Wiens 2002); that is, they move between discrete locations with different temperatures (Torgersen et al. 1999). Such movement among "patches" can be important to individual survival and population persistence because thermal conditions at discrete locations can be highly temporally variable (Dugdale et al. 2013) and spatially complex (Fullerton et al. 2015). Management of stream thermal regimes should carefully consider the spatiotemporal distribution and dynamics of thermal conditions at scales that are relevant to the species in the region (Fausch et al. 2002) at durations that are relevant to the rates of system change and recovery from disturbance.

### 4.3.2. Amphibians and Reptiles

Few studies address the effects of altered thermal regimes on stream-associated amphibians and reptiles, which currently limits the level of specificity to which reliable management recommendations can be made. However, some important insights are possible and these are best discussed in the context of breeding habitat: 1) amphibians that breed in the flowing portions of stream networks, and 2) amphibians and reptiles that breed in or use off-channel stillwater habitats associated with stream networks.

Instream-breeding amphibians (giant salamanders, *Dicamptodon* spp.; tailed frogs, *Ascaphus* spp.; and torrent salamanders, *Rhyacotriton* spp.) are generally described as having low thermal requirements (Bury 2008). However, those requirements are often characterized solely in terms of critical thermal maxima (Brattstrom 1963; Claussen 1973; Brown 1975; Bury

Giant salamanders (*Dicamptodon* spp.) can be found in small western Washington streams/Eric Lund, WDFW

2008), while stream temperatures in which these species are found are considerably lower than those maxima (invariably  $\leq 61^{\circ}\text{F}$  [ $16^{\circ}\text{C}$ ]; e.g., Brattstrom 1963; Welsh 1990; Welsh and Lind 1996; Pollett et al. 2010). Moreover, water temperatures at which these species first become stressed are entirely unknown. Several studies demonstrate higher density or relative abundances (Stoddard and Hayes 2005; Pollett et al. 2010) of amphibians at the margin of their temperature maxima although the mechanism responsible for this effect is unclear. Similar to fish, identifying critical effects of temperatures on amphibians is complicated by a host of potential variables, e.g., younger life stages frequently have cooler temperature requirements (de Vlaming and Bury 1970; Brown 1975) than older life stages. Importantly, very little research has been conducted on the effects of altered thermal regimes on the timing of life history events, such as the time of hatching, and indirect effects, such as possible ecological temporal mismatches, altered predator-prey relations, and disease frequency and effect (e.g., Hari et al. 2006), that would be useful for identifying important conservation and management actions.

Amphibians and reptiles that breed or utilize riverine off-channel stillwater habitats (e.g., oxbow lakes and permanent and seasonally flooded riverine wetlands) associated with stream networks generally have warmer thermal requirements than instream breeding amphibians. For stillwater-breeding amphibians, thermal requirements vary as a function of the thermal tolerance limits of a specific life stage (often eggs and embryos), which determine the seasonal interval in which they lay eggs. For example, Northern Red-legged Frog *Rana aurora* embryos have the lowest critical thermal maximum of any North American frog (about  $68^{\circ}\text{F}$  or  $20^{\circ}\text{C}$ ) (Licht 1971), and they oviposit in late winter, at which time surface water temperatures of stillwater habitats rarely if ever put its embryos at risk. Except for our two turtle species (Western Pond Turtle *Actinemys marmorata* and Western Painted Turtle *Chrysemys picta*) and selected garter snake species *Thamnophis*, especially the Common Garter Snake *T. sirtalis* and the Western Terrestrial Garter Snake *T. elegans*, few reptiles utilize aquatic habitats in the Pacific Northwest. These reptiles have

*Riparian corridor/Ned Pittman, WDFW*

thermal requirements that are more elevated than the temperatures generally found in stillwater habitats except during the warmest part of summer. For this reason, aerial basking (basking out of water) at daytime temperatures that are warmer than water temperature can be critical for these species for effective digestion of food or production of eggs. This pattern is especially important for turtles that need aquatic aerial basking sites isolated from predators, which in most stillwater habitats are provided by large downed wood with relatively level accessible surfaces above the water line (Holland 1994).

### 4.3.3. Invertebrates

Few studies have examined the effects of altered thermal regimes on stream-associated invertebrates in the Pacific Northwest. However, broad relationships between the geographic distributions of invertebrates and their thermal tolerance have been reported (Beschta et al. 1987; Moulton et al. 1993) as have changes in emergence timing and asynchronous emergence among sexes due to small increases in summer temperatures (Li et al. 2011), demonstrating the importance of temperature to invertebrates. Stream temperature can affect invertebrate density, growth, size at maturation, and sex ratios and the effects often

differ among species (Hogg and Williams 1996). Altered stream thermal regimes appear to have important effects on many invertebrates and, subsequently, on stream food webs. Indirect effects such as altered predator-prey relations and disease frequency may also be important but have not been well studied. Riparian ecosystem management for aquatic invertebrates is also constrained by a general lack of information on their geographic distribution.

### 4.3.4. Species Sensitivity Summary

Management of vegetation in riparian ecosystems can affect stream temperatures and, subsequently, fish, amphibian, and invertebrate abundance and survival. Stream temperature influences important food web and energetic interactions between fish, amphibians, and invertebrates in multiple direct ways and likely in more subtle but relatively unstudied indirect ways (Baxter et al. 2005). The effects of thermal regime has received little study for amphibians and invertebrates. Fortunately, our understanding of the mechanisms that affect stream thermal regime can provide useful guidance in the absence of better information.

## 4.4. Land Use Effects

### 4.4.1. Urbanization

**T**here have been very few studies specifically relating urbanization to riparian ecosystem function and subsequent effects on stream thermal regimes (Paul and Meyer 2001). Clearly, urbanization related changes to riparian areas can be similar to riparian changes associated with agriculture and forestry as far as stream temperature is concerned, e.g., removal of shade, reduction in large wood inputs. Urban areas have additional issues that can affect stream temperatures including heat island

effects, and inputs of wastewater and runoff from impervious surfaces (Kinouchi et al. 2006; Hester and Doyle 2011). Some of these complicating factors may contribute to the absence of detectable effects on stream temperatures studies in some comparative studies (Wahl et al. 2013). Nonetheless, urbanization is considered to have adverse effects on stream temperatures (LeBlanc et al. 1997; Finkenbine 1998), especially when riparian functions are affected (Booth et al. 2001). To protect stream thermal regimes in urban settings, conservation efforts should focus on maintaining riparian functions, mitigating anthropogenic changes to hydrology, and preserving watershed connectivity (e.g., movement of water, sediment, wood, nutrients, and species).

## 4.4.2. Agriculture

In comparison to urbanization studies, studies of the effects of agricultural practices on riparian ecosystems or subsequent effects on stream thermal regimes are fairly abundant, especially for grazing lands (e.g., Li et al. 1994; Tait et al. 1994; Maloney et al. 1999; Zoellick 2004) and crop lands (e.g., Waite and Carpenter 2000). Studies examining the effects of agriculture, particularly livestock grazing, generally find stream temperature increases associated with disturbance of the riparian ecosystem (Zoellick 2004; Webb et al. 2008). Livestock use of streamside areas can increase a stream's exposure to direct sunlight by reducing shade from streamside vegetation (Li et al. 1994). Livestock can also reduce the amount of undercut banks and increase stream channel width through trampling and vegetation removal (Belsky et al. 1999; Chapter 2). Channel widening can also result in reduced depth, which can exacerbate warming (Poole and Berman 2001). However, results of observational studies are mixed, with occasional absences of predicted detectable increases in stream temperature due to changes in riparian ecosystems as a result of agriculture (e.g., Tait et al. 1994) and wide variation in effect on riparian

---

## *Studies of the effects of land management on riparian functions and stream temperatures confirm the importance of riparian ecosystems to stream thermal regimes.*

---

vegetation among locations and types of agriculture (see Maloney et al. 1999). Importantly, Zoellick (2004) found that riparian vegetation can recover after removal of the disturbance agent (e.g., livestock). For crop lands, the importance of riparian ecosystem attributes, e.g., vegetation width, height and density, on stream temperatures have been documented (Waite and Carpenter 2000) and, similar to grazed lands, effects differ widely among locations (Benedict and Shaw 2012).

## 4.4.3. Forestry

Relative to urbanization and agriculture, many studies in the Pacific Northwest have examined the effects of forest management on stream temperatures. Decades of research have frequently documented increased stream temperature due to forestry practices (Olson and Rugger 2007), and our understanding of the mechanisms by which forest practices affect stream temperatures is well developed (Beschta et al. 1987; Groom et al. 2011). Most studies find that forestry, especially when riparian vegetation is disturbed, results in higher stream temperatures than in less disturbed locations (Li et al. 1994), however, exceptions to this pattern are not uncommon. For example, Liquori and Jackson (2001) found stream temperatures 3 to 7°F (1.5 to 4°C) greater in stream reaches surrounded by dense riparian forests compared to downstream reaches

adjacent to scrub-shrub riparian communities. Many of the studies of the effects of forestry on stream temperatures include consideration of some of the components and structures that affect stream thermal regimes identified by Boyd and Kasper (2003) and Poole and Berman (2001). For example, Liquori and Jackson (2001) suggest that their results are due to lower width-to-depth ratio, higher rates of hyporheic or groundwater exchange, and greater amounts of shade in shrub-scrub associated reaches. Maloney et al. (1999) found that much of the variation in their results (in mostly agricultural settings) was explained by reach length, shade, elevation, aspect, and especially by stream gradient and air temperature. Similarly, Kiffney et al. (2003) and Janisch et al. (2012) described the influence of groundwater and hyporheic exchange on their results.

#### 4.4.4. Land Use Summary

Studies of the effects of land management, especially the many studies of forestry, on riparian functions and stream temperatures confirm the importance of riparian ecosystems to stream thermal regimes. Additionally, they emphasize the high degree of variability among locations of the functions that affect stream thermal

regimes, even among adjacent stream reaches, that so often produce variable results. Unfortunately, studies that examined the effects of land management on the complete thermal regime of a stream are lacking. Such studies could be especially valuable because the cumulative effects of riparian ecosystem or upland management on stream temperatures can dominate local effects (Chapter 8). Further, most studies use only a few statistics that describe peak or average temperatures, usually during summer. Such statistics are useful, but have limited ability to address dynamic, water quality parameters including temperature (Poole et al. 2004) related to species needs. Thus, predicting the effects of land management on other thermal attributes (e.g., duration or frequency of stressful temperatures) or during other seasons when thermal exposure can significantly affect some species (e.g., overwinter incubation) is difficult. Similarly, even cumulatively, the relatively small number of studies and their skewed geographic distribution (i.e., most are on low-order streams in maritime regions) constrain our ability to provide broad and precise generalizations or make accurate predictions to other locations. Conservation efforts for maintaining stream thermal regimes must be based on our understanding of direct and indirect mechanisms of stream heating affected by human activities, wise use of statistical models relating shade and stream temperature across the watershed until mechanistic models become available, and preserving watershed connectivity (e.g., movement of water, sediment, wood, nutrients, and species).

### 4.5. Conclusions

**S**cientific understanding of the structure and function of streams and the importance of thermal regimes has improved substantially since the publication of Knutson and Naef (1997). This understanding underscores the need to consider temperature statistics other than the daily maximum temperature during summer. We now have mechanistic,

*Light through alder tree canopy/Ned Pittman, WDFW*

deterministic models that can accurately predict changes in stream temperatures for specific locations due to specific management actions in the riparian ecosystem. We are also better able to set directional or qualitative expectations for cumulative effects on temperatures at the spatial extent of watersheds. However, quantitative information needed to run mechanistic, deterministic models to make site-scale predictions (e.g., surface water and groundwater flows and temperatures) is expensive to collect and thus are rarely used in management settings. Further, even the most capable stream temperature predictive models are limited by the assumption that the channel structure remains relatively stable (e.g., cross-section shape will not change) even though there is strong evidence that riparian and some types of upslope management affects channel stability (Chapters 2 and 3) at least in some reach types.

Scientific models and most observational studies find that shade from riparian vegetation can affect stream thermal regimes, particularly by lowering peak temperatures during summer. Recent monitoring studies have found substantial variation in the thermal sensitivity of apparently similar stream reaches. The use of improved monitoring tools (e.g., digital temperature loggers), more robust study designs e.g., Before-After-Control-Impact designs (Eberhardt 1976; Stewart-Oaten et al. 1986), more powerful statistical analyses (Gomi et al. 2006; Isaak et al. 2014), and longer study durations have improved our ability to detect effects of riparian management actions on stream temperatures. Importantly, better understanding of the structure and function of streams, especially the importance of surface, ground, and hyporheic water flows on stream temperatures, has allowed scientists to identify likely causes for failures to detect effects of riparian shade reductions on stream temperatures.

*Giant salamander (Dicamptodon spp.) egg cluster/Jack Armstrong, WDFW*

Scientific understanding of the importance of stream temperatures on aquatic species has improved substantially over the past two decades, especially for salmonids. Most studies provide useful descriptions of some direct effects of exposure to high temperatures on specific life stages. Laboratory and field studies demonstrated the importance of temperature on fish survival and allowed for comparisons among species, populations, and life stages, and thus the identification of those that are likely most sensitive to heat stress. They have also demonstrated substantial differences in sensitivity among species, populations, and life stages which make developing simple thermal standards challenging and likely inadequate for management. Several recent studies have described effects of prolonged exposure to elevated, but non-lethal, temperatures and altered thermal regimes. These studies demonstrate some of the complexity of this management challenge. Even when altered thermal regimes do not have immediate lethal effects on species, there are costs or trade-offs, such as changes in growth, survival, productivity, and energetic requirements. Detecting such effects is beyond the scope of most studies and will often require long-term, comprehensive monitoring of populations through several life cycles. Such studies will likely need to be conducted at spatial

*Salmon eggs in Morse Creek/Steve Boessow, WDFW*

extents and durations that account for fish behavior, such as daily and seasonal movement among locations where temperature regimes differ.

Relatively few studies that describe the effects of temperatures or thermal regimes on reptiles, amphibians or invertebrates have been completed. Most studies of these taxonomic groups have simply identified seasonal thermal preferences in the field or the effects of acute temperature in laboratory settings. Such studies are valuable for identifying thermally sensitive species, but are insufficient for management. Further, we found no study that addressed ecological interactions that might be mediated by riparian condition on a stream's thermal regime.

Studies generally show that the effects of urbanization, agriculture, and forestry on watershed and riparian ecosystems result in warmer summer stream temperatures, an expectation consistent with the conceptual model. Importantly, these land uses often include surface water routing to streams (e.g., roads and ditches) that can change the timing, intensity, duration, and temperatures of stream flows. The changes in

temperature detected differed among regions, land uses, and studies. The relatively low number of studies and high variability among study results limits our ability to accurately predict outcomes in unstudied locations and precludes us from reliably calculating a mean (i.e., expected) resulting temperature change, even for a specific temperature statistic. Of the studies we reviewed, most were designed to detect an effect using a specific stream temperature statistic (e.g., mean daily maximum summer temperature) rather than changes in the stream's thermal regime. This limits the inferences that can be made, especially from studies in which anticipated temperature changes were not detected, and to make reliable, precise generalizations from study results.

Although we have sound understanding of the composition, structure, and functions that affect stream thermal regimes, substantial uncertainty remains regarding the effects of any specific riparian management action on stream thermal regimes in most locations. That uncertainty is amplified by our relative lack of understanding at large spatial and long temporal extents for which few studies have been

completed. Recovery of stream temperatures due to shade from vegetation regrowth can occur in less than a decade following disturbance (D'Souza et al. 2011), but recovery rates differ widely among locations due to differences in stream size and components that control rates of vegetation re-establishment and growth (Gecy and Wilson 1990; D'Souza et al. 2011). Although scientists are very certain that temperatures and thermal regimes are important to many aquatic species, relatively little is known about ecological interactions (e.g., predator-prey relations), behaviors (e.g., movement among locations of different temperature), and indirect effects (e.g., effects on the rates and severity of disease). These interactions may be very important. For example, Lawrence et al. (2014) suggest that riparian restoration in some locations might prevent extirpation of Chinook Salmon and restrict the expansion of non-native fish in some locations by maintaining relatively cool stream temperatures. Such uncertainties often compound and should be addressed explicitly when making management decisions, especially when the decisions can have important, lasting effects (Harwood and Stokes 2003). Management of riparian ecosystem composition (e.g., vegetation species, side channels) and structure (e.g., longitudinal and lateral connectivity) can importantly benefit aquatic species. Management for such beneficial effects might prove especially important as our climate continues to change.

The state of the science regarding stream thermal regimes is uneven. On the one hand, we have a very good understanding of the physics of stream heating and cooling. We understand the relative magnitudes of direct and indirect effects of ecosystem changes on stream thermal regimes and have the ability to quantify these effects given enough time and resources. Shade provided by riparian vegetation is generally considered the single most important, albeit not the only, process of the system that humans can directly effect. These findings are undisputed. On the other hand, because thermal regimes are affected by a variety of factors and their interactions, stream temperatures are difficult to

precisely predict on the basis on any single factor alone (e.g., shade). Thus, predicting stream temperature based solely on shade removal or buffer width will likely always suffer from imprecision. In addition to this prediction challenge, and despite the fact that we know suitable water temperatures are critical to the persistence of aquatic species, we are only now beginning to understand how aquatic organisms interact with and are impacted by changes in the stream thermal regime. The combination of what we know and do not know about how changes to stream thermal regimes affect aquatic species and how human activities can affect those regimes makes conservation in the face of a changing climate particularly challenging.

# Chapter 5. Pollutant Removal

By: Jeffrey L. Ullman and George F. Wilhere

## 5.1. Introduction

**T**he capability of riparian areas to remove certain pollutants from runoff has been known to scientists for over 60 years (e.g., Trimble and Sartz 1957). Understanding the complex processes and associated factors that affect the pollutant removal function of riparian areas is essential for developing management strategies that will protect aquatic ecosystems. Management of riparian areas for pollutant removal differs from the other ecological functions discussed in this document in that the primary focus is on mitigating activities occurring outside the riparian area. The pollutant removal function is unique in that it only exists in the presence of human activities that generate polluted water, and it is only necessary when runoff from upland activities threaten to degrade water quality.

This chapter summarizes key information relevant to riparian pollutant removal function. First, a general background is presented on the main processes and related site-level factors affecting the transport and fate of nonpoint source pollutants in riparian areas. Next, the biological impacts, common sources, *in situ* chemistry, transport pathways, and mitigation are reviewed for five types of pollutants—sediments, excess nutrients, metals, pesticides and other organic compounds, and pathogens. Last, a summary of what is currently known about the relationships between riparian buffer width and pollutant removal is provided. Riparian buffer is not synonymous with riparian area. Riparian area is an ecological designation that is synonymous with riparian ecosystem (see Chapter 1). Riparian buffer is a management designation, and a buffer may be narrower or wider than the riparian ecosystem.

Yellowjacket Creek/George Fornes, WDFW

This chapter only addresses nonpoint-source chemical pollutants that interact with riparian areas. Hence, it does not deal with “thermal pollution” effects on water temperature (see Chapter 4), which is another important water quality parameter. Similarly, it does not deal with pollutants routed via roads, ditches, and drains into urban and suburban stormwater runoff systems, or with polluted water routed to rivers and streams via agricultural tile drainage.

While the scientific literature reviewed here includes information collected during the 1970s and 1980s, when scientists first started to rigorously investigate the removal of pollutants by riparian areas (Correll 1997), more recent findings are highlighted. Decades of research have revealed that the ecosystem structures and processes responsible for pollutant removal functions of riparian areas are complex, spatially and temporally variable, and dependent on site-level environmental conditions. This complexity and variability are the main reasons for inconsistent results found in the published research and the lack of definitive recommendations regarding the structure and size of riparian buffers required for pollutant removal. Nevertheless, general trends in research findings can guide policy makers and resource managers to management strategies that address these uncertainties and lead to adequate protection of water quality.

## 5.2. The Pollutant Removal Function of Riparian Areas

Water quality refers to the physical, chemical, and biological characteristics of water that indicate a waterbody's

suitability to meet human needs or habitat requirements for fish and wildlife. Riparian areas exert a significant influence on water quality due to their position between terrestrial and aquatic ecosystems. Pollutants in dissolved, chemical, or suspended solid forms are transported by water from uplands to surface waterbodies, and while passing through riparian areas contaminated water undergoes a variety of physical, chemical, and biological processes that reduce pollutant concentrations. The processes in riparian areas affecting pollutant transport and fate are complex and often interrelated. Riparian areas slow surface runoff and increase infiltration of water into the soil, thereby enhancing both deposition of solids and filtration of water-borne pollutants. Riparian areas also intercept and act on contaminants in subsurface flow through dilution, sorption<sup>1</sup>, physical transformation, chemical degradation, or volatilization by various biogeochemical processes and through uptake and assimilation by plants, fungi, and microbes.

There is overwhelming evidence in the scientific literature that riparian buffers reduce nonpoint source water pollution for a variety of pollutants—including sediments, excess nutrients, metals, organic compounds such as pesticides, and pathogens. Management activities can enhance the physical, chemical, and biological mechanisms that reduce the flow of polluted waters to river and streams.

<sup>1</sup> Sorption or “to sorb” is a physical and chemical process by which one substance becomes attached to another. It encompasses two processes adsorption and absorption. Adsorption is the binding of molecules or particles to a substance's surface. The reverse of adsorption is desorption. Absorption is the filling of minute pores in a substance by molecules or particles.

*Riparian buffer widths for pollution removal need not be one-size-fits-all/U.S. Dept. of Agriculture, National Agriculture Imagery Program*

However, the science is very clear that results vary considerably depending on local conditions, and that the configuration of a riparian buffer may effectively remove one type of pollutant while having minimal effect on another. Although riparian management can reduce significantly the quantity of pollutants entering surface waters, riparian areas are not sufficient by themselves to fully mitigate pollution from nonpoint sources. Thus, it is critical to view pollution control from a holistic, watershed perspective that also manages contaminated runoff at its source, i.e., upland areas subjected to various intensive land uses: forestry, agriculture, commercial, and urban, suburban, and rural residential. Nevertheless, maintaining functional riparian areas is essential for reducing nonpoint source pollution and must be a key component in any suite of management actions focused on water quality.

## 5.3. Processes Influencing the Pollutant Removal Function

**R**iparian areas are consistently shown to remove a variety of nonpoint source pollutants, such as those originating from agricultural lands, urban areas, construction sites, and forestry operations. However, the effectiveness of riparian buffers is highly variable (Hickey and Doran 2004; Lee et al. 2004, Anbumozhi et al. 2005; Zhang et al. 2010). Inconsistencies among research results can be explained by the multi-dimensional heterogeneity of riparian ecosystems; the complex, interconnected processes that act on contaminant transport and fate; and the variety of research methods employed. Many site-specific factors contribute to this variability,

including riparian buffer width, slope, topography, surface and subsurface hydrology, soil properties, riparian vegetation, and adjacent upland characteristics. Of all these factors hydrology, soil, and vegetation play dominant roles governing pollutant transport and fate (NRC 2002). The following sections discuss the effects of these three site-level characteristics on the pollutant removal function of riparian areas.

### 5.3.1. Hydrology

Hydrologic regimes at the terrestrial-aquatic interface impart a particularly significant influence on the attenuation of pollutants by riparian areas. Three principal pathways govern water movement through these systems: 1) overland flow and shallow subsurface flow from adjacent uplands, 2) groundwater flow, and 3) instream water movement that includes hyporheic exchange as well as flood conditions (NRC 2002). Each of these flow paths can act as conduits for pollutant transport to aquatic ecosystems depending on site-specific conditions and pollutant type. Furthermore, seasonal stream flows, fluctuating water tables, and intermittent flooding create a dynamic environment that subjects pollutants to a range of biogeochemical processes.

Upland sources of water often originate as precipitation. During and immediately after a precipitation event, water from upland areas follows different flow paths to the stream channel, each contributing differently to pollutant transport and fate. Overland flow can be either infiltration-excess<sup>2</sup> (Hortonian overland flow) or saturation-excess<sup>3</sup> overland flow. Water that enters the soil profile can also travel downslope in shallow subsurface flow (interflow) through the unsaturated zone<sup>4</sup>. Depending on site-specific conditions, water in one of these flow paths may switch to another.

Collectively these flow paths are commonly termed hillslope runoff. Under certain circumstances, such as in the presence of deep, well-drained soils that facilitate percolation, portions of the shallow subsurface flow can reach the groundwater table and resume transport in the groundwater system. These pathways extend into riparian areas before reaching a surface waterbody.

As overland flow travels through the landscape it can pick up pollutants that can be in either particulate or soluble form. When water infiltrates the soil surface, suspended particulate matter and associated contaminants are entrapped at the soil surface, almost exclusively limiting the form of pollutants that are transported through the subsurface to soluble forms that remain in solution. However, recent research highlights the significance of colloid-facilitated transport as an additional means by which contaminants can move through the subsurface (Sen and Khilar 2006; Bradford and Torkzaban 2008). Colloidal forms (particles ranging from 1 to 1,000 nm) can remain dispersed in solution and exhibit characteristics resembling solutions. This behavior can consequently mobilize substances that tend to sorb to soil particles or organic matter that would otherwise not be able to move through the subsurface. While the fundamental physics and chemistry of this mechanism is understood, the contribution of colloids to pollutant migration through the soil profile is unresolved. Essentially no literature exists on the role of colloids in riparian areas, contributing to uncertainty in predicting the ultimate fate of associated pollutants.

The fundamental variables of interest regarding groundwater are flow rate and travel time, which influence natural chemical and biological processes that remove soluble pollutants, such as sorption to soils, microbial degradation, and plant uptake (Vogt et al.

<sup>2</sup> Infiltration-excess overland flow occurs when water enters a soil system faster than the soil can absorb or transport it, such as when precipitation exceeds the infiltration capacity of the soil.

<sup>3</sup> Saturation-excess overland flow occurs when the soil becomes saturated, and any additional precipitation results in runoff.

<sup>4</sup> The unsaturated zone is also known as the vadose zone. It extends from the ground surface to the water table. Beneath the water table is the zone of saturation.

2012). As groundwater approaches the stream margin biogeochemical activity increases, and this gradient contributes to temporal and spatial variability in solute fluxes (Hayashi and Rosenberry 2002). It should be noted that groundwater exhibits a different geochemical composition than shallow subsurface flow that originates from precipitation events. Groundwater samples typically have a greater specific conductance (related to salinity), higher mineral content and elevated pH (Landmeyer 2011). Differences in chemical composition and biogeochemical activity are likely to manifest differences in pollutant removal from groundwater.

The hyporheic zone is the region beneath and alongside the streambed that represents the groundwater-surface water interface. While hydrologists have a solid understanding of most other hydrologic processes occurring in riparian areas, understanding of the exchanges between groundwater and in-channel surface waters is considerably less (UKEA 2009; Gu et al. 2012). Hyporheic flow patterns are multifaceted and influenced by the pressure gradient at the stream margin, (micro)morphology of the channel,

the spatial distribution of hydraulic conductivity along the streambank, and the water exchange rate between the river and the riparian area (Kalbus et al. 2009; Lewandowski 2011). The complexity of the hydrologic regime is further compounded by seasonal variations, and at times intra-seasonal oscillations, in the direction of water flow (Wroblicky et al. 1998), as well as instances where ambient movement of deeper groundwater flows near the interface. Despite the confounding nature of the hyporheic zone, it is vital to consider hyporheic exchange when discussing subsurface fluxes of pollutants, as this zone is a direct link to streams through which contaminants can be transported to lotic systems (Gordon et al. 2004).

Not only does the hyporheic zone play a critical role in regulating pollutant fluxes from riparian areas to the adjacent lotic environment, the heterogeneous structure at the interface, an oscillating water table, and shifting flow regimes exert a significant influence on biogeochemical cycling. The fluctuating water table alters oxygen concentrations and oxidation-reduction (redox) potential, and the flow regime provides a continuous source of reactants. This dynamic environment allows for anaerobic and aerobic processes to occur simultaneously and in close proximity (Wang et al. 2014). The strong hydraulic and biogeochemical gradients that result from mixing of the subsurface water coming from riparian areas and the surface water of the stream channel create biogeochemical hot spots that exhibit disproportionately high reaction rates compared to the surrounding matrix (McClain et al. 2003). For instance, the convergence of shallow subsurface flow and groundwater at the stream interface can generate hot spots of denitrification. Similarly, hot moments represent brief periods of elevated reaction rates relative to longer periods (e.g., during a rainfall event). Later sections of this chapter discuss this concept in more detail.

---

*As groundwater approaches a streambank, biogeochemical activity increases. Groundwater flow rate and travel time through the riparian area influence natural chemical and biological processes that remove soluble pollutants.*

## 5.3.2. Soils

Soils play a critical role in influencing the transport and fate of pollutants in riparian areas. Soil texture and structure act as primary hydrologic regulators, significantly influencing the movement and distribution of contaminants. Comprised of a complex mixture of solid, liquid, and gaseous phases, riparian soils provide a heterogeneous matrix that supports plant and microbial communities. The solid phase encompasses mineral and organic particles of differing sizes and chemical composition that can sorb metals, organic chemicals, and other pollutants, thereby preventing them from migrating to the stream channel. The multiplicity and interaction of various biogeochemical processes in riparian soils contribute greatly to pollutant removal.

Unlike upland soils that are derived from terrestrial parent material, riparian soils primarily develop through the deposition of sediments that originate from various upstream sources. These alluvial deposits establish a heterogeneous patchwork of stratified sediments of

different textures, which influences the movement of waterborne contaminants. Huggenberger et al. (1998) provide a good review of the geomorphology and characterization of alluvial soils, but a brief description is warranted here to provide a background related to the movement of contaminants through riparian soils. Deposits of clay, silt, sand, and gravel, and continual disturbance by seasonal high flows and occasional extreme flood events, create a complex mosaic of soil microenvironments that can vary considerably both vertically within the soil profile and along the length of the stream channel (Malanson 1993). A general trend can be observed where coarser sediments are deposited along steep-gradient streams while finer particles are washed downstream and deposited along low-gradient reaches as stream energy dissipates and wider floodplains develop (BLM 2003). Soil particle size also tends to decrease moving away from the stream edge (Huggenberger et al. 1998). This vertical, longitudinal, and lateral spatial structure results in disparate hydrologic conditions, and corresponding differences in pollutant fate, at locations in close proximity.

*Rough-skinned Newt Taricha granulosa/Renee Kinnick, WDFW*

The soil microenvironments described above influence hydrologic conditions, which consequently affect pollutant transport. Soil texture and structure dictate water storage capacity and retention, flow paths and hydraulic conductivity. Coarse textured soils enable a greater hydraulic conductivity that shortens hydraulic residence time in the riparian area, thereby reducing the period in which attenuation mechanisms can act on soluble contaminants before they reach the stream channel. Water may percolate below the root zone and limit potential interactions between vegetation and pollutants in deep, well-drained soils, such as those commonly found in forested riparian areas in humid climatic regions (NRC 2002). However, the root zone intercepts subsurface flow to a greater degree in forested riparian areas that exhibit shallow soils overlying a confining layer (e.g., shallow aquiclude). Overland flow that predominates in arid environments often undergoes limited infiltration due to a tendency for riparian soils to exhibit low permeability in these regions, which allows much of the runoff and associated waterborne contaminants to enter the stream with minimal attenuation (NRC 2002; Buffler et al. 2005).

Altered soil structure can influence pollutant attenuation (Vervoort et al. 1999). Compaction, for instance caused by over-grazing or vehicular traffic, and accompanying structural changes and surface soil instability can lead to diminished infiltration and amplified overland flow (Bohn and Buckhouse 1985; McInnis and McIver 2001). Soils with low infiltration rates typically exhibit a diminished capacity to retain pollutants in riparian areas (Johnson and Buffler 2008). Subsurface soil structure influences water movement and distribution in the unsaturated zone, affecting pollutant transport. Subsurface soil structure also impacts soil aeration and plant root growth, which have ramifications on pollutant fate. Preferential flow in soil macropores represents another facet of soil structure that affects pollutant removal (Allaire et al. 2015). Preferential flow of water through large connected void spaces in soils, which result from fractures, animal burrows and other

processes, can enhance subsurface pollutant transport to river systems (Angier et al. 2002; Fuchs et al. 2009; Menichino et al. 2014). Alluvial deposits in riparian areas can further increase the connectivity of subsurface flows with stream channels, increasing lateral contaminant transport toward the stream channel. Preferential flow paths diminish the potential for contaminant sorption by both reducing interactions with soil particles and associated sorption sites and contributing to a higher flow velocity that reduces sorption kinetics. Although preferential flow paths have been a familiar concept in the field of soil science for some time, the recognized importance of these conduits has increased in recent years. This enhanced understanding is particularly important for controlling pollutants such as phosphorus that historically were not considered to undergo much, if any, subsurface transport (Angier et al. 2002; Fox et al. 2011a).

Artificial preferential flow also can be created by tile drains that are used by agricultural operations to remove excess water from the soil profile. Tile drains have been shown to enhance the movement of nutrients and herbicides from agricultural fields to streams, bypassing the natural attenuation processes that would have otherwise reduced the movement of these agrochemicals to aquatic ecosystems (Guan et al. 2011; Vidon and Cuadra 2011; Jaynes and Isenhardt 2014).

In addition to playing an integral role in influencing the hydrologic linkage between upland areas and the stream channel, riparian soils provide a dynamic framework that regulates biogeochemical processes that act on contaminants. Soluble pollutants that have entered the soil profile, either from subsurface flow from upland areas or through infiltration in the riparian area, are subject to a variety of processes. Contaminants prone to sorption can be retained within the soil profile of the riparian area, reducing their potential of migrating to the stream channel. Chemicals typically have a greater affinity for clay minerals or organic matter, and thus the attenuation due to sorption will vary depending on

Riparian area along White River/Alan Bauer

the soil composition. Microbial assemblages in riparian soils can contribute to the assimilation, transformation, and degradation of a range of chemicals. Anaerobic conditions in saturated soils found in riparian areas differ considerably from the aerobic environments of adjacent uplands, altering the redox potential. The fate of numerous contaminants is influenced strongly by the redox potential of the soil and associated microbial communities. Fluctuating water tables can alter the redox state, resulting in seasonal variations in chemical species distributed within the riparian area. Although broad generalizations can be made, the literature highlights that temporal changes in soil complexities are not well understood (NRC 2002).

Vegetative communities are also impacted by soil conditions in riparian areas. Plant species exhibit habitat preferences that follow soil moisture gradients across riparian areas. The influence of vegetation on contaminant fate and transport will be discussed in the next section. However, it is salient to note here that soil compaction and other disturbances can lead to invasive plant species that can degrade riparian ecosystem

function in relation to pollutant attenuation. Disturbed soils can lose their native species diversity and develop more homogenous stands of an exotic species (e.g., Himalayan Blackberry *Rubus armeniacus*) that often do not have the same vegetative density or root structure as the native population, thereby altering riparian area efficacy in pollutant removal.

### 5.3.3. Vegetation

Riparian vegetation also plays a critical role in attenuating pollutant transport to surface waters. Plants physically alter the movement of water and associated contaminants, provide habitat for microbial communities that assimilate and transform contaminants, and influence soil redox conditions that govern many biogeochemical cycles. Plant root systems provide bank stabilization, which reduces the direct introduction of sediments into aquatic ecosystems via streambank erosion. Soil stabilization also limits erosion and gully formation that can result from overland flow moving through a riparian area. In addition, forested riparian

*Vegetated buffers reduce nonpoint source pollution to rivers and streams/U.S. Dept. of Agriculture, National Agriculture Imagery Program*

areas have been shown to enhance instream processing of contaminants, including nutrients and pesticides (Sweeney et al. 2004). This section provides a brief overview of the influence vegetation has on pollutant attenuation in riparian areas and identifies critical points to consider when developing management plans. A number of focused review articles present further details on riparian vegetation-hydrology interactions and mechanisms by which plants can attenuate contaminants in riparian areas (e.g., Tabacchi et al. 2000; Williams and Scott 2009; Dosskey et al. 2010).

The high vegetation density inherent in streamside ecosystems serves a critical function in modulating overland flow and amplifying infiltration. The stems of grass and herbaceous groundcover, trunks of woody vegetation, and downed wood create resistance to overland flow, slowing it, and causing deposition

onto and infiltration into the soil profile (Fisher and Binkley 2000; Schuster and Grismer 2004). Vegetation also helps maintain soil structure by increasing soil macropore formation through root growth and decay, which further enhances soil permeability. Soluble contaminants present in overland flow enter the soil column, augmenting attenuation through the various mechanisms discussed throughout this chapter. The reduced velocity of the overland flow caused by the riparian plant community causes suspended particles to settle out of the water column, reducing the transport of sediment and sediment-borne pollutants to the stream. Similarly, lower velocity flows will limit erosion within the riparian area, reducing potential contributions to stream sediment loads and avoiding gully formation, which concentrates overland flows and short circuits pollutant attenuation. A dense overstory canopy will further reduce erosion by intercepting precipitation

that would fall directly onto bare soil, and a dense plant community also reduces erosion of riparian soils by diminishing the velocity of runoff and floodwaters (Schultz et al. 2000).

Vegetation also increases soil surface roughness by producing herbaceous litter and woody debris, and by altering micro-topography, which slows surface flow and enhances infiltration of water. In contrast, sites with exposed mineral soil tend to exhibit low surface roughness that limits infiltration, and these sites are susceptible to increased transport to streams via overland flow.

Vegetation also influences the hydrologic behavior of subsurface and groundwater flow through streamside areas. Root uptake and transpiration by both herbaceous and woody plants can modify subsurface flow and

soil moisture regimes in the unsaturated zone under unsaturated conditions. These alterations not only influence pollutant transport through riparian soils, but also affect redox conditions that govern biogeochemical transformations. Deeper-rooted plants can impact groundwater levels by reducing the pressure head at the water table through direct uptake or by extracting water along a water potential gradient. Hence, trees can cause daily or seasonal changes to water table levels, a phenomenon more prevalent in drier climates (Landmeyer 2011). Correspondingly, contaminant fluxes from riparian areas to surface waterbodies may exhibit similar diurnal and seasonal patterns. Water uptake by roots can similarly form a hydraulic barrier that creates an upward water flow through the soil profile that can reduce pollutant leaching and inhibit contaminant plumes from spreading horizontally (Pilon-Smits 2005).

*Chinook salmon Oncorhynchus tshawytscha/Morgan Bond*

Riparian management strategies often emphasize the effectiveness of forested riparian areas for protecting water quality. However, research over the last two decades reveals that forests are not always the most effective vegetation for removing pollutants. Results can vary between sites, but research has shown that grass buffers (also called vegetative filter strips or grass filter strips) can yield similar reductions in sediments and sediment-borne pollutants (Correll 1997; Hawes and Smith 2004; Dosskey et al. 2010). Grasses and

While vegetation modulates water flow, it is vital to recognize the interconnected nature between riparian plant communities and hydrologic regimes. Riparian plant communities are determined largely by their adaptation to high moisture environments. Groundwater often represents a primary water source for riparian plants, principally trees and deeper-rooted flora. Consequently, alterations in groundwater regimes can have a detrimental impact on species diversity, density, and distribution, especially in drier regions where vegetation is typically concentrated along a narrow band of suitable soil moisture conditions (NRC 2002). Dramatic changes to plant communities can significantly limit the pollutant removal function of a riparian area. Thus, managers should consider the interrelationships between vegetation and subsurface hydrology. Kuglerová et al. (2014) expounded on this theme in a recent review examining the effects of forest management on groundwater processes and resultant water quality. The authors concluded that logging operations in riparian areas and hydrologically connected upland forests can alter groundwater regimes and affect water quality. They recommended site-specific riparian management where wider buffers would be implemented at critical groundwater discharge locations but narrower buffers would be allowed at sites lacking groundwater flow paths.

similar plants create a dense vegetative obstacle that slows overland flow, promotes deposition of sediments and attached pollutants, and provides an opportunity for the plants and associated microbes to capture soluble contaminants that enter the soil profile (Dillaha et al. 1989). Filter strips often serve as an effective alternative for protecting water quality from pollutants generated by upland activities where it is impractical to implement forested riparian areas, such as adjacent to agricultural fields, in urban settings, or along highways.

According to Lacas et al. (2005), much of the sediment removal effected by grass filter strips occurs mainly as a result of sedimentation immediately upslope of the strip in an area of still water that builds up against the strip's outer boundary. Furthermore, they note, the deposit formed upslope can expand into the filter strip, and that sediment deposition can increase to the point of forming channels that concentrate overland flow and induce the formation of water pathways with high velocities.

The primary drawback of a vegetative filter strip is that it addresses only pollutant removal and does not provide the other functions of forested riparian areas such as shading, large wood, and bank stability. Furthermore, grasses have a relatively shallow root

structure and thus vegetative filter strips are not as effective in removing pollutants from groundwater. In contrast, trees inherently have a deeper root zone that can effectively intercept subsurface flow and often reach shallow groundwater. Therefore, forested riparian areas can be more effective at removing soluble pollutants in subsurface and groundwater flow through plant uptake and by associated microbial communities that act on the pollutants in the rhizosphere. Considering both situations, structurally diverse riparian areas that contain a combination of grasses, shrubs and trees provide a more robust system for mitigating a range of pollutants (Fischer and Fischenich 2000). A similar concept was proposed by Welsch (1991), who presented a three-zone model that considered an herbaceous filter strip between uplands and the start of the riparian area, followed by a managed forest, and culminating with an undisturbed forest immediately adjacent to the streambank.

Vegetation in riparian buffers also provides a range of phytoremediation processes, wherein plants and associated microbial populations remove, contain, degrade or eliminate pollutants. Investigations on the phytoremediation potential of riparian vegetation to attenuate nutrients have been conducted for some time and results are well documented. The management of vegetation specifically as a pollutant treatment technology for organic compounds and metals has gained acceptance in general over the last couple of decades (Pilon-Smits 2005), but studies on phytoremediation specific to riparian areas remains fairly limited. However, recent research suggests that the promotion of specific plant species to attenuate organic chemicals and metals in riparian areas can be used to treat localized areas of concern (e.g., chemical spills, industrial sites, mine tailings). Design of a phytoremediation treatment system depends largely on the three primary factors identified by Susarla et al. (2002) that govern contaminant uptake and distribution in plants and the surrounding soil system:

physicochemical characteristics of the pollutant (e.g., polarity, lipophilicity), environmental conditions (e.g., soil moisture, pH), and plant characteristics (e.g., available enzymes, root structure). Specifics on the phytoremediation potential of different pollutant classes in riparian areas will be discussed later in the respective sections of this chapter, while more detailed descriptions of phytoremediation are readily found in a large number of scientific reviews (e.g., Salt et al. 1998; Pulford and Watson 2003; Pilon-Smits 2005; Sarma 2011).

## 5.4. Specific Pollutants

For the purposes of riparian area management, we are most interested in five types of water pollutants: sediments, excess nutrients (in particular, nitrogen and phosphorus containing compounds), metals (in particular copper), toxic organic compounds (especially pesticides), and pathogens (especially those related to agricultural animal waste). The physical, chemical, and biological processes through which riparian areas remove these pollutants from water vary tremendously. Consequently, the degree to which riparian areas can remove each of these pollutants, and thereby protect aquatic ecosystems, varies significantly. The following sections describe the complicated processes and mechanisms involved in determining removal efficacy of specific pollutants by riparian areas.

---

*Vegetation in riparian buffers provides a range of phytoremediation processes, wherein plants and associated microbial populations remove, contain, degrade or eliminate pollutants.*

## 5.4.1. Sediments

Sediment transport in streams is a natural process, but excessive sediment loads can significantly degrade water quality. The impact of sediments on aquatic organisms has been researched extensively for many decades, and can consist of lethal, sub-lethal and behavioral effects (Newcombe and MacDonald 1991). Sediments that settle out of the water column can smother gravel and cobble streambeds that are essential for salmonid spawning and habitat for benthic macroinvertebrates and other organisms that form critical links in stream food webs. For example, the filling of interstitial spaces in coarse sediment matrices with fine sediments are thought to reduce or eliminate refuge and foraging habitat for selected life stages of stream-dwelling amphibians (Welsh and Ollivier 1998). Increased turbidity levels, indicative of suspended particles, can elicit physiological stress in fish through

gill abrasion, impaired immune function and lowered growth rates (Redding et al. 1987; Au et al. 2004). High suspended sediment loads reduce visibility, which limits fish foraging ability and influences predator avoidance reactions (Redding et al. 1987). Aquatic vegetation and periphyton can be reduced due to diminished light penetration. Sediments also impart indirect effects on aquatic organisms. Elevated turbidity decreases the water albedo (reflectiveness), which increases the fraction of radiant energy absorbed by the water and increases stream temperature, leading to corresponding reductions in dissolved oxygen concentrations. Furthermore, sediments serve as a transport mechanism for other pollutants, carrying attached contaminants from upland sources to the stream channel. Soil particles that harbor legacy contaminants perpetuate water quality problems, such as those caused by DDT in some Washington streams despite this pesticide being banned in 1972 (Ecology 2007).

*Restored vegetation in riparian area to capture pollutants in runoff/U.S. Dept. of Agriculture, National Agriculture Imagery Program*

While the extent of these detrimental effects is largely a function of concentration and duration, and there is little agreement on the degree of ecological risk in the literature, sediments are a ubiquitous pollutant that many scientists regard as the worst form of pollution in aquatic ecosystems (Newcombe and MacDonald 1991; Waters 1995).

Erosion rates in uplands can be significantly increased by agricultural activities, construction sites, deforestation, and other land uses. Riparian areas effectively remove soil particles carried from upland areas via overland flow by slowing overland flow velocities, promoting sediment settling, and acting as sediment sinks<sup>5</sup>. Mass wasting (also referred to as mass movement, mass failure, or slope movement), wherein large masses of soil and geologic material move downslope into a stream, acts as another potential sediment source in hilly or steep mountainous environments. Although limited in spatial distribution, this geomorphic process can overwhelm the sediment removal capacity of riparian areas.

Our understanding of the riparian area's sediment removal function will be enhanced with a basic understanding of sediment erosion and transport processes. Briefly, the impact of falling raindrops can loosen soil particles via splash erosion. Overland flow picks up soil particles and transports them downslope through sheet erosion. Generation of concentrated flow paths results in rill erosion, which enhances sediment delivery and increases erosion rates through flow that is on the order of a few centimeters deep. Gully erosion develops when deep, narrow channels form, leading to increased erosion and more rapid sediment delivery. It is important to prevent the formation of rill and gully erosion entering riparian areas because channel formation extending into riparian areas short-circuits

sediment removal and represents a direct conduit from terrestrial to aquatic systems. Merritt et al. (2003) provide an extensive review of various erosion and sediment transport models that can be employed to determine the potential sediment loads that could enter a riparian area.

While the upland hydrologic regime acts as a principal driver governing the movement of eroded soil particles, the aforementioned erosion mechanisms can be significantly tempered by intact soil cover. This can be accomplished by vegetation overlying a dense cover of herbaceous litter and woody debris. Vegetation increases surface roughness which slows surface flow and enhances water infiltration, both of which promote the settling out of sediments (Figure 5.1). Muñoz-Carpena et al. (1999) showed that spacing between vegetation is the most important parameter in sediment attenuation in riparian buffers, although soil characteristics, sediment load, and slope also play prominent roles.

---

*Agriculturally generated nitrogen continues to present an issue, and it is becoming increasingly apparent that smaller hobby farms and lawn fertilizers used in suburban and urban areas can lead to severely degraded water quality.*

<sup>5</sup> Streambank erosion, channel incision, and surface erosion in riparian areas present other potential sediment sources. As this chapter focuses on the removal of pollutants generated by upland activities, these geomorphological processes are outside the scope of this chapter. However, it should be noted that riparian vegetation can increase bank stability, thereby decreasing erosion along the stream channel (see Chapter 2).

Figure 5.1 Efficacy of riparian buffer in removal of sediment from runoff. The amount of suspended sediment in runoff increases through sheet erosion of upland soils. Vegetation, woody debris, and organic litter in riparian buffer reduce flow velocity. Reduced flow velocity and increased water infiltration into soils causes deposition of suspended sediments. Sediments not removed from runoff increase turbidity and can smother gravel or cobble streambed habitats.

Riparian buffer widths required for sediment attenuation vary considerably depending on the site-specific conditions (e.g., slope, area of adjacent uplands, drainage paths, vegetation density). Sediment particle sizes are also a consideration in buffer width design – larger particles are deposited within the first 10 to 33 ft (3 to 10 m) of a buffer but smaller particles settle out at greater distances (Sheridan et al. 1999; Syversen et al. 2001; Dosskey et al. 2002; Yuan et al. 2009). The potential quantity of overland flow should also be a consideration when determining buffer widths, and hence, upland area should also factor into the determination of buffer width. Leeds et al. (1994) suggested that on agricultural lands the ratio of field drainage area to buffer area should be no greater than 50:1, and for consistently higher water quality the ratio should be on the order of 3:1 to 8:1. From research conducted on forested lands undergoing timber harvest, Clinton (2011) concluded that leaving a forested riparian buffer of 33 ft (10 m) would sufficiently reduce sediment transport to the adjacent stream, assuming responsible timber harvest practices, although greater widths have been recommended depending on the circumstance (Castelle et al. 1994). Furthermore, the relationship between buffer width and sediment attenuation is non-linear, necessitating a disproportionate increase in width to achieve an incremental increase in sediment removal. This relationship was described in a literature review of research on riparian buffers conducted by Sweeney and Newbold (2014). They concluded that a sediment removal efficiency of about 65% is typical for 30 ft (10 m) buffers but an 85% removal efficiency required more than twice that width, about 100 ft (30 m).

## 5.4.2. Excess Nutrients

Excess nutrients, in this context referring specifically to nitrogen and phosphorus, have long been recognized as

significant water quality impairments. Eutrophication, the nutrient enrichment of aquatic systems, promotes algal blooms that shift community structure. Subsequent bloom die off leads to oxygen deficiency in the water column as oxygen is consumed by microorganisms during the decay of the excess organic matter. Hypoxia can have devastating consequences on aquatic animal communities, killing immobile organisms (e.g., clams) and mobile species (e.g., fish) that are not able to escape the deoxygenated zone. Excessive accumulation of cyanobacteria (formerly known as blue-green algae), resulting from shifts in nutrient ratios in the water, can release cyanotoxins which can cause dermal reactions, gastroenteritis, liver and kidney poisoning, and neurological impacts in humans or animals following water contact. Canine deaths due to cyanotoxin exposure have been confirmed throughout the country, with Washington reporting the highest number of cases among 27 states (Backer et al. 2013). In some cases, selected nutrients are toxic at concentrations within typical fertilizer application ranges. For example, embryos of the highly aquatic Oregon Spotted Frog *Rana pretiosa*, a federally threatened species in the Pacific Northwest, all died after 15-day exposure to nitrite ( $\text{NO}_2^-$ ) concentrations lower than 2 mg/L (Marco et al. 1999).

Fertilizers and manures are major sources of excess nutrients entering riparian areas. Wastewater discharges and leaking septic tanks introduce nutrients to riverine systems, but those sources fall outside the scope of this review. Agricultural activities have long been blamed as the biggest nonpoint source for nutrients. The enormous contribution of phosphorus to the eutrophication of surface waters led to extensive promotion of various best management practices (BMPs)<sup>6</sup> for reducing off-field transport of phosphorus. Nevertheless, there has been a general lack of improvement in water quality of many receiving

<sup>6</sup> In general usage "best management practice" (BMP) means one or more practices that are determined to be an effective and practicable means of preventing or reducing the amount of pollution generated by nonpoint sources to a level compatible with water quality goals. Under Washington State regulations, BMP means physical, structural, and/or managerial practices approved by the Washington Department of Ecology that, when used singularly or in combination, prevent or reduce pollutant discharges (WAC 173-201A-020).

streams. In addition to existing agricultural sources of phosphorus, it is increasingly evident that “legacy phosphorus” from past activities that accumulated in watersheds contributes to current water quality problems (Jarvie et al. 2013). Agriculturally generated nitrogen continues to present an issue, as it can leach through the soil and move with shallow groundwater flows through riparian soils and enter receiving waters. It is also becoming increasingly apparent that smaller hobby farms and lawn fertilizers used in suburban/urban areas can lead to severely degraded water quality (Cheng et al. 2014).

For a thorough discussion of nitrogen and phosphorus dynamics in natural, undisturbed riparian areas see Chapter 6. For this chapter it is salient to note the differing biogeochemical cycles exhibited by nitrogen and phosphorus: nitrogen displays complex transformations between various species including atmospheric forms whereas phosphorus undergoes relatively simple shifts between soluble, sorbed, precipitate and organic forms. Nitrogen and phosphorus are often casually grouped together as nutrients, but this discrepancy in chemical behavior leads to significantly different considerations when assessing their removal by riparian areas.

## Nitrogen

Due to its soluble nature in its aqueous forms, a significant portion of the excess nitrogen entering streamside areas will enter riparian soils either through infiltration or via groundwater transport. Nitrogen then can undergo attenuation through a variety of mechanisms. It is widely accepted that denitrification acts as the primary pathway for removing nitrate ( $\text{NO}_3^-$ ) from water in riparian areas (Fennessy and Cronk 1997; Cey et al. 1999; Wang et al. 2014). This process is governed by specific denitrifying bacteria that use nitrate during anaerobic respiration, reducing it to the gaseous forms of nitric oxide (NO) and nitrous oxide ( $\text{N}_2\text{O}$ ) and ultimately molecular nitrogen ( $\text{N}_2$ ). These

gaseous species can then volatilize in harmless forms to the atmosphere and be completely eliminated as a potential pollutant. This process requires the presence of a shallow water table, anoxic conditions, denitrifying bacteria and an available carbon source—conditions commonly associated with riparian areas. Hydric soils, despite occupying a limited area within riparian areas, are important sites of anaerobic activity that promote denitrification. If groundwater bypasses riparian soils then nutrient pollution of surface waters may occur despite the presence of a riparian buffer (Burt et al. 1999). In a highly cited critical review of research on nitrate removal in riparian areas, Hill (1996) asserted that understanding denitrification requires a better understanding of groundwater interactions with riparian vegetation and soils.

Plant uptake of dissolved nitrogen in subsurface flows moving through riparian areas provides an additional mechanism that can remove considerable amounts of nitrate. A significant difference from denitrification though is that vegetative uptake is often viewed as transient storage for nitrogen because nitrogen assimilated by plants will be reintroduced to the ecosystem following leaf senescence or plant death. Both grasses and trees have been widely shown to remove nitrogen in riparian areas, but studies have yielded contradictory observations and conclusions regarding which vegetation type is more effective (Groffman et al. 1991; Osborne and Kovacic 1993; Schnabel et al. 1997). A meta-analysis performed to assess the key riparian variables responsible for nitrogen removal concluded that forested buffers exhibited the greatest propensity for nitrogen uptake, and surpassed the efficacy of both grasses and communities composed of both trees and grass (Zhang et al. 2010). Although this study did not end the debate, many researchers believe that deeper and more expansive root structure allows trees to take up greater proportions of nitrogen. A riparian area’s age may also be a variable affecting nitrogen removal. Cors and Tchon (2007) evaluated denitrification enzyme activity in two

riparian areas of different ages: 6 and 20 years old. They found the older system was significantly more effective at denitrification, which was attributed to a greater accumulation of carbon.

Research focusing on hot spots and hot moments has provided a more nuanced understanding of nitrogen dynamics in riparian areas. Hot spots and hot moments that develop in the hyporheic zone are increasingly being recognized as a contributing mechanism to nitrogen attenuation (McClain et al. 2003; Vidon et al. 2010; Gu et al. 2012). A landmark paper by Hedin et al. (1998) exemplified the concept of enhanced nitrogen removal at hot spots along the soil-stream interface in a mixed forested-agricultural watershed. A first-order stream exhibited two converging primary flow paths, one consisting of shallow subsurface flow containing high concentrations of chemical reducers (i.e., dissolved organic carbon,  $\text{CH}_4$ , and  $\text{NH}_4^+$ ) and the other a near-stream upwelling of deep groundwater containing high concentrations of oxidizers (i.e.,  $\text{NO}_3^-$ ,  $\text{N}_2\text{O}$ , and  $\text{SO}_4^{2-}$ ). A zone of high denitrification resulted that was less than 3 ft (1 m) wide and remained active for the two-year study period. Hedin et al. (1998) suggested that nitrate removal via denitrification could be sustained depending on the spatial location of high flow pathways, the propensity of the chemical environment to support rapid denitrification, and the availability of oxidizable carbon. Furthermore, they recommended that management actions enhancing natural carbon inputs could be adopted to optimize nitrate removal by denitrification.

## Phosphorus

Unlike nitrogen, phosphorus possesses a binding affinity for soil particles and typically enters riparian areas adsorbed to soil particles carried by overland flow. Hence, phosphorus removal is closely connected to sediment removal by riparian areas. A comprehensive review of phosphorus dynamics in grass buffer strips surmised that that optimum phosphorus retention occurs in filter strips that are at least 16 to 33 ft (5 to 10

*Unknown species of crayfish in the Deschutes River/Steve Boessow, WDFW*

m) wide (Dorioz et al. 2006), but this recommendation is debatable. It is generally recognized that a positive correlation exists between buffer width and phosphorus retention in riparian areas, and hence, buffers greater than 33 ft (10 m) offer greater removal efficacy. Independent studies have consistently found 60% to 80% phosphorus removal by buffers roughly 15 to 53 ft (4.6 to 16.3 m) wide (Dillaha et al. 1989; Vought et al. 1994; Lee et al. 2003). Forested riparian ecosystems assessments have yielded less consistent results, with studies showing phosphorus removal ranging from 30% to 80% in deciduous riparian areas (Lowrance et al. 1984; Cooper and Gilliam 1987). This discrepancy corresponds with the premise that a robust stand of grass provides better attenuation of sediments and associated pollutants than forested riparian areas.

Even though these results appear convincing at first glance, a significant proportion of the body of research consists of short-term studies that fail to account for changes in riparian function over time. While it can confidently be stated that riparian areas offer effective short-term control of sediment-bound phosphorus, uncertainty exists regarding their long-term efficacy. Filter strips receiving sediment loads are well known to become less effective over time due to internal erosion and sediment accumulation. The continual incorporation of phosphorus into surface soils presumably would lead to a saturation of the system that could not only decrease removal of new phosphorus entering the

riparian area, but also lead to release and export of dissolved phosphorus to the stream that had previously been stored in riparian soils (Muscutt et al. 1993). Some studies have reported significant removal of soluble phosphorus in surface runoff (Peterjohn and Correll 1984). However, contradictory reports indicate little retention of soluble forms, with the majority moving through the area in surface runoff (Daniels and Gilliam 1996). Plants take up some of the phosphorus in the riparian soils, but this mechanism is not nearly as significant in removal as it is for nitrogen. Increased removal of soluble forms could potentially be achieved with various amendments, such as biochar (charcoal used as a soil amendment), that could enhance phosphorus sorption (Zhang et al. 2014).

A relatively new research topic related to phosphorus attenuation focuses on subsurface transport of soluble phosphorus forms. It was long accepted as dogma that phosphorus did not leach or move through the soil profile. Although scattered findings contradicted this view during the preceding decades (e.g., Peverill et al. 1977), this conviction remained recalcitrant and was still taught in university soil courses up until the last decade. This belief has now been dispelled by increasing evidence that phosphorus can move through

the soil profile, particularly in coarse textured soils. A preponderance of the recent research on this topic has been conducted in upland soils, but the findings are relevant for riparian areas and are particularly true in coarse alluvial soils. This has been demonstrated by the rapid transport of soluble phosphorus forms through preferential flow paths (Fuchs et al. 2009). This movement can serve as an important transport mechanism that should be considered when determining potential phosphorus fluxes reaching the stream channel. Although extensive literature exists on phosphorus cycling in a variety of settings, relatively little information is available on phosphorus dynamics in the hyporheic zone and further research is needed to understand phosphorus flux through this interface between the stream and groundwater flowing through riparian areas (Zhang 2014).

### 5.4.3. Metals

Metals (as well as metalloids that share similar properties, such as arsenic) are elements naturally found in geologic material. They enter the environment either through natural weathering processes or through anthropogenic activities. Localized metal deposits can result in elevated concentrations in streams that can be hazardous to biota. Metal pollution in aquatic ecosystems appeared as a serious environmental issue on a wide scale in the late 19th and early 20th century due to increasing industrial and mining activities. Contamination sources have grown over time to include a range of other activities, the most pertinent to this discussion on riparian areas being runoff from urban and agricultural lands. While mining activities present significant metal inputs into certain streams in Washington, protecting water quality from these sources requires the implementation of specific remediation techniques that are outside the scope of this chapter.

---

*While it can confidently be stated that riparian areas offer effective short-term control of sediment-bound phosphorus, uncertainty exists regarding their long-term efficacy. Riparian filter strips are well known to become less effective over time.*

Metals present a significant environmental hazard that can lead to a variety of health issues in plants and animals. While some metals are essential elements required for normal growth and development of biota, these can also impart toxicological issues when concentrations exceed a given threshold. Among other health effects, metals can be carcinogenic, cause reproductive problems, and interfere with the normal function of the heart, bones, intestines, and kidneys. While debate continues over the specific mechanisms associated with metal toxicity in plants, it is generally recognized that oxidative stress represents a primary driver that results in cellular damage (Pinto et al. 2003). Some heavy metals bioaccumulate and biomagnify, which leads to elevated concentrations exhibited at higher trophic levels (Boening 2000). The propensity for metals to bioaccumulate can be magnified by biologically mediated transformation into organometallic complexes, such as methylmercury. Metal toxicity is often related to the chemical species formed, which often relates to their bioavailability. For instance, chromium(III) compounds are not considered a significant health risk while chromium(V)

is a well-known carcinogen. Similarly, metal complexation with dissolved organic carbon often inhibits their bioavailability.

While copper's detrimental environmental impacts have been recognized for many decades (Sprague and Ramsay 1965), it has received increased attention in recent years as toxicity symptoms have become more pronounced. Copper is an essential mineral for organisms, contributing to enzymatic and metabolic function, but toxic effects have been observed at all levels of the aquatic food chain when it exceeds particular concentrations. Copper has been shown to have detrimental effects on plants, retarding growth at concentrations as low as 1.0 part per billion (ppb) and impeding photosynthesis at 5.0 ppb levels (USEPA 1980). While reductions in algal production can theoretically exert an indirect effect on zooplankton by limiting their food source, copper can impart a lethal effect on these organisms at low parts per billion levels (Ingersoll and Winner 1982). Similarly, significant mortality has been shown to occur in benthic macroinvertebrates at similar copper

*Juvenile salmon need clean water/Ned Pittman, WDFW*

concentrations (Clements et al. 1992). Copper presents a litany of issues to fish. Lethal concentrations vary considerably between fish species and fluctuate depending on environmental conditions. Sub-lethal effects are conveyed at lower concentrations, which include hindering osmoregulation, weakening immune response, altering enzymatic and metabolic activity, impairing olfaction (sense of smell), altering migration patterns and predator avoidance behavior, and modifying hatch rates (Lortz and McPherson 1977; Sorensen 1991; Rougier et al. 1994; Baldwin et al. 2003; Monteiro et al 2005; Sandahl et al. 2007; McIntyre et al. 2012). Synergistic impacts that occur when copper is present in combination with other pollutants highlights the current concern over this element (Hecht 2007). Effects similar to those observed in fish have been recorded in amphibians following exposure to rather low concentrations of copper ions ( $\text{Cu}^{2+}$ ). For example, the concentration of copper at which half of larval Northern Leopard Frogs *Rana pipiens* would die following a seven-day exposure was estimated at 0.067 mg/L (Redick and La Point 2004). The same study revealed lethargy, loss of equilibrium, and loss of appetite at copper concentrations of 36 ppb. A widespread pattern in copper exposure studies with amphibians is a general impairment of predator evasion behaviors (Garcia-Muñoz et al. 2011).

Anthropogenic copper inputs to the environment include those of other metals, but what sets copper apart are two significant sources. The first is the agricultural use of copper-based pesticides. Copper sulfate and other copper-based pesticides are frequently used as a fungicide to protect a variety of crops, including fruits and potatoes. The second is the release of copper from vehicle brake pads. This unique source has received considerable attention as an environmental hazard worldwide, and has led to the 2010 adoption of Washington State's Brake Material Friction Act (RCW 70.285) that is phasing out copper in automobile brakes (Straffelini et al. 2015). Copper can also enter the environment through atmospheric deposition,

which is a potential pathway in industrial and mining regions (USEPA 1980). These sources introduce copper into the environment as a nonpoint source pollutant, which makes copper very different from other metals. While the following discussion will continue to refer to metals in general, the reader should recognize that the nonpoint source nature of copper makes it the primary metal of concern in Washington in regards to attenuation in riparian areas.

Metals form various inorganic and organic species, the nature of which directly relates to its bioavailability and mobility through a riparian area. Metal speciation is driven through complex biogeochemical processes. Environmental conditions and the chemical nature of the surrounding constituents play a significant role in dictating the form that a metal might take. This is particularly relevant to riparian areas where fluctuating water tables alter redox conditions, and correspondingly metal dynamics in riparian soils. Daily oscillations related to the photocycle, for instance, have been shown to occur in aquatic ecosystems as a result of biogeochemical interactions involving temperature, acidity, and biofilms (Nimick et al. 2011). Consequently, zinc, manganese, and cadmium can increase several-fold between late afternoon and early morning. In contrast, arsenic undergoes the opposite diel pattern; meanwhile copper and lead do not undergo regular diel cycling.

The metal species resulting from soil acidity and redox conditions can form precipitates, exhibit an affinity to clay minerals and oxide/hydroxide compounds, and thus be more readily retained in riparian areas. Conversely, metals stay in solution as more mobile forms that leach and move toward the stream. Typically, metals more readily enter solution under acidic conditions. Meanwhile the ionic strength of the water (a measure of the concentration of all the ions in solution) presents a confounding variable in these processes. The impact of other ions manifests through enhanced metal desorption from soil particles with increasing

salinity. Carbonates in riparian soils promote metal retention by buffering acidity (i.e., preventing increased acidity), limiting metal solubility, and forming insoluble precipitates with metals.

Organic constituents in soil-water systems also play a major role in metal fate and transport processes. It has been clearly understood for some time that humic substances, a classification of complex and heterogeneous macromolecules that represent a substantial component of natural organic matter, have the capacity to bind significant amounts of metals (Reuter and Perdue 1977). While association of metal ions with soil organic matter can retain metals, humic substances can act as colloids and contribute to colloid-enhanced movement. The environmental factors and mechanisms involved in metal-humic interactions are multifaceted, but it is salient to recognize the impacts that organic matter in riparian soils can have on the movement of metals to the stream channel. A more detailed explanation of the inorganic and organic factors that influence metal behavior is presented in a review by Du Laing et al. (2009), which includes a specific focus on riparian areas.

Unlike organic contaminants that can degrade, metals are recalcitrant and removal in riparian areas depends largely on retention. Although the brief description of metal chemistry provided here elucidates the primary factors that affect their movement in the environment, management practices to enhance their attenuation are limited, and metal mobility will be driven overwhelmingly by environmental conditions. An exception to this statement is phytoremediation.

Phytoremediation of metals offers promise as a means to enhance metals removal in riparian areas. Although significant research on this process did not start in earnest until the late 1990s, since then hundreds of scientific papers have been published on the topic. Correspondingly, there is a plethora of review articles (e.g., Ghosh and Singh 2005; Sarma 2011; Koptsik 2014;

Laghlimi et al. 2015). Four classes of phytoremediation can influence metal attenuation in soil, including phytoextraction (removal of metals from the soil-water system by plants), phytostabilization (minimizing metal transport and sequestering them in the soil near the roots), phytovolatilization (uptake and transpiration by plants; this process is primarily limited to mercury and arsenic), and rhizofiltration (sorption, concentration and precipitation of metals in the root mass). Of these, the first two mechanisms are the most effective in attenuating metals (Laghlimi et al. 2015). In general, trees are a more effective form of vegetation due to their size, perennial nature, and the depth of root growth. Different metals will accumulate in different parts of a tree. For instance, copper tends to be immobilized and retained principally in the roots while zinc moves into the branches and leaf mass (Pulford and Watson 2003). Some plant and tree species act as hyper-accumulators that are tolerant of high metal concentrations in soils and can amass metals in their tissues through detoxification mechanisms (Sarma 2011). These species could be preferentially planted in areas where metals are a particular concern to help attenuate metal movement to the stream channel. As leaves will fall to the ground, riparian management could include the periodic removal of vegetative debris to off-site locations to avoid subsequent movement to the stream. Often there is no need to plant nonindigenous plants as a variety of common native riparian vegetative species can provide phytoremediation capabilities. For instance, willows (*Salix* spp.) have been shown to attenuate various metals in riparian areas to great effect (Bourret et al. 2009; Zhongmin et al. 2012).

Soil amendments offer another form of “green remediation” that has been increasingly used in soil systems since the turn of the century. A wide variety of amendments can be used either to mobilize metals by promoting uptake via phytoextraction or to immobilize (stabilize) metals in a solid phase. For instance, chelating agents have been applied at sites around the globe to enhance desorption, while phosphate

Tilton River/George Fornes, WDFW

fertilizers are common amendments intended to intensify metal sorption and form precipitates. Several topical reviews describing assorted soil additives have been published that provide more detail on this *in-situ* remediation technique (e.g., Bolan et al. 2014; Mahar et al. 2015). Similarly, over the last decade biochar has seen increased application in the context of attenuating metals (Ahmad et al. 2014). Although studies on the use of soil amendments to attenuate metals in riparian soils are limited, recent findings showed that additions of 11 different materials, such as biochar, bentonite, cement bypass kiln dust, and limestone to a floodplain soil could provide a potential remediation technique (Rinklebe and Shaheen 2015). An evaluation of the amendments in riparian soils heavily contaminated with copper (over 3,000 mg/kg) showed that most of the additives shifted the geochemical forms of copper through either increased sorption or by transformation to more plant available forms. Although the authors concluded that the low amendment rates that could practically be applied would inadequately immobilize copper, the increased copper concentration found in grass tissues at the same site indicates a means of enhanced phytoremediation.

Clearly, the use of soil amendments requires further field verification in riparian areas, but this approach to enhancing natural attenuation mechanisms shows promise.

## 5.4.4. Pesticides and Other Organic Compounds

An extensive array of organic contaminants exists in the environment that can threaten water quality in aquatic ecosystems. This category of compounds describes molecules that contain carbon covalently bonded to other elements, and includes both naturally derived and synthetic chemicals. This chapter focuses on anthropogenic compounds that exert a toxic effect on aquatic organisms.

The multitude of organic chemicals makes it impractical to touch on each class here, but common examples that present environmental health risks in aquatic habitats include polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and pesticides. While the detrimental effects of many of these pollutants have been recognized for some time, studies continually identify emerging contaminants of concern ("emerging" does not only connote new compounds, but also chemicals that have been in use without realizing the extent of their toxicity). For instance, hazards associated with flame retardants, such as polybrominated diphenyl ethers (PBDEs), have been highlighted over the last decade (Covaci et al. 2011; Ye et al. 2015). Recent research emphasis also has been placed on a variety of trace organic compounds, including pharmaceuticals and personal-care products (PPCPs), as it is now recognized that these chemicals can exert negative impacts on fish and other aquatic organisms at both the individual and population levels even at extremely low (e.g. parts per trillions) concentrations (Mueller 2004; Kümmerer 2009a; Kümmerer 2009b; Luo et al. 2014). In addition, there is growing awareness that while individual pesticides may have little or no effect

when examined alone, that same pesticide as part of a pesticide mixture may be lethal to amphibians (Hua and Relyea 2014).

While only a brief discussion was provided above on the various organic pollutants that act as environmental contaminants, a little more information on pesticides is warranted, as they are more likely to be used in uplands and transported into riparian areas. Pesticides consist of any substance that is used to control fungal, plant, or animal pests. These chemicals represent a broad range of different chemicals that are derived from various sources such as plant extracts (nicotine, pyrethrum, neem oil), inorganics (e.g., copper sulphate; inorganic pesticides will not be discussed here), and synthetics. Synthetic pesticides are themselves a broad class that includes legacy organochlorines (chlorinated hydrocarbons such as DDT), organophosphates (e.g., Malathion), phenoxyacetic acids (e.g., MCP), carbamates (e.g., carbaryl), and neonicotinoids (e.g., imidacloprid). Pesticide pollution of streams can impact non-target organisms resulting in a wide variety of physiological and ecological problems (Mann et al. 2009), including altered growth (Alvarez and Fuiman 2005) and reproduction (Moore et al. 2007), altered community dynamics (Fleeger et al. 2003), and the loss of species (Relyea and Diecks 2008).

The ecological impacts of organic pollutants on aquatic organisms vary considerably, depending on not only the contaminant type but also the environmental conditions. Various compounds can be carcinogenic (causing cancer), mutagenic (altering genetic material and fomenting mutations), and teratogenic (stimulating abnormalities). Organic pollutants can also act as endocrine disrupting chemicals (EDCs), adversely impacting development, reproduction, neurologic, and immune system function in humans and wildlife (Colborn et al. 1993). Endocrine disruption has emerged as a key issue as studies have identified more cases of detrimental impacts, such as the discovery of atrazine-induced feminization of male Northern Leopard Frogs at

very low concentrations (Hayes et al. 2003). This finding is controversial, but it has increased awareness that many organic compounds have potentially unrecognized endocrine-disrupting effects. Some organic contaminants, such as halogenated hydrocarbons, are capable of bioaccumulating in individuals and biomagnify up the food chain (Rahman et al. 2001).

To further complicate potential risk, pesticides rarely occur singly in aquatic environments. For example, a comprehensive decadal assessment of 178 streams in agricultural, urban, and mixed-land use watersheds found two or more pesticides more than 90% of the time and ten or more pesticides 20% of the time (USGS 2006). Ecological and toxicological research is increasingly recognizing the complexity of contaminant mixtures, which may have antagonistic, additive, or synergistic interactions in biota (Cedergreen 2014). For example, combining the pesticides diazinon and Malathion inhibits brain activity, and therefore swimming performance in fish at concentrations more than 50 times lower than the concentrations that cause an impact when these pesticides are used singly (Laetz et al. 2013). Although the examples given focused on pesticides, mixtures of hydrocarbons originating from roadways, parking lots and other locations can also be found in urban watersheds, including pollutants such as PAHs that originate from coal-tar-sealed parking lots (Scoggins et al. 2007). Amalgamations of these urban generated organic contaminants have been shown to impart both sub-lethal and lethal effects on aquatic organisms and disrupt stream communities (PSAT 2007; Scoggins et al. 2007; Spromberg et al. 2016).

The sheer number of different sub-classes of pesticides makes it impractical to provide information on the chemical behavior of all the potential contaminants that might be encountered in riparian areas. Pesticide pollution is extremely complex due to the multitude of types, the wide range of molecular sizes, the diversity of chemical structures, and the ability of these compounds to react and transform into new products. However,

some basic information on organic compounds will enable a better understanding of the effects riparian buffer size and structure have on pesticide pollutants. It is essential to identify the physicochemical properties of organic contaminants to adequately assess fate and transport pathways through riparian areas. Specific gravity, water solubility, vapor pressure, and partitioning coefficients such as the octanol/water partition ( $\log K_{ow}$ ) and organic carbon partition coefficients ( $K_{oc}$ ) all serve as predictors of a substance's potential mobility and attenuation in riparian areas.

Natural organic matter has a significant impact on the degree of attenuation riparian soils impart on pesticides. The aforementioned  $K_{oc}$  represents the ratio of the amount of chemical adsorbed to the soil to the amount of chemical that remains in solution, related to the mass fraction of organic matter in the soil (Delle Site 2001). This value essentially indicates the affinity of a pollutant to soil organic matter and is a predictor of its potential mobility through the soil, where higher  $K_{oc}$  values correlate to less mobile organic contaminants and low  $K_{oc}$  values correlate to more mobile organic contaminants. Hydrophobic, nonpolar compounds, such as PAHs, are typically associated with particles in soil-water systems, whereas polar contaminants often exist in dissolved forms that exhibit a greater propensity for movement through the ecosystem.

The relationship between pesticides and their respective  $K_{oc}$  values can be confounded by humic substances, which are a heterogeneous mixture of chemically complex macromolecules that comprise a substantial component of natural organic matter. Humic substances have long been known to exert a significant impact on the movement of organic contaminants (Hayes 1970; Khan 1972). These amorphous compounds, which are classified into humic acid, fulvic acid, and humin fractions based on their molecular size and chemical behavior, can effectively bind organic pollutants and present either water-insoluble entities that are retained in the soil column or water-soluble colloids that can

facilitate transport through riparian soils to the stream channel. Even when present in small quantities, these chemically reactive compounds can dramatically influence the binding, persistence, and translocation of organic pollutants. The interactions between humic substances and organic contaminants are beyond the scope of this chapter, but their potential to affect  $K_{oc}$  values by up to an order of magnitude is salient to predicting their attenuation by riparian buffers (Grathwohl 1990; Kopinke et al. 2001). Nevertheless, in general the attenuation of organic pollutants in riparian areas is positively correlated with soil organic matter.

Pesticides and other organic pollutants can also be retained in riparian areas through sorption to mineral components in the soil, although often to a lesser extent than to organic matter (Delle Site 2001). The surface area of soil particles enhances the binding of organic pollutants, which increases with finer soil textures such as those found in clays. The mineral composition of the soil particles also influences binding affinity by offering different forms of attachment sites. Those compounds that do not attach to soil material are susceptible to leaching, which can result in them entering the groundwater and being transported to the stream. Contaminants associated with inorganic particulates are usually much less bioavailable, although they can become bioavailable if particles are ingested by biota (Moermond et al. 2004).

Pesticides and other organic pollutants can undergo abiotic and biotic transformations that further compound the complexity of their chemistry. Abiotic processes include degradation due to chemical reactions such as hydrolysis (Mitchell et al. 2014; Mitchell et al. 2015). Biotic transformations include biologically mediated reactions, such as bacterial metabolism. Although the potential for biodegradation is dependent on the chemical structure of the contaminant, indigenous soil bacteria can use many organic compounds as a metabolic substrate. Repeated exposure to the same type of pesticides can foster microbial communities that

become contaminant specialists (Vidon et al. 2010). For example, soils receiving repeated applications of the pesticide 2,4-D harbor more 2,4-D-degrading microbes than similar plots receiving fewer applications (Gonod et al. 2006). Similarly, PAH-degrading bacteria were more abundant in rain gardens receiving stormwater runoff than upland control plots (LeFevre et al. 2012). The robust microbial communities found in riparian areas, resulting from conditions discussed previously, helps attenuate many organic compounds in riparian soils. Being biologically mediated, however, the degradation rates will fluctuate seasonally depending on temperature and soil moisture.

Phytoremediation by riparian vegetation provides an additional attenuation mechanism for organic contaminants. Although phytoremediation has received significant interest over the last two decades, the literature contains few papers on this method specific to pesticides in riparian areas. However, the principles are the same as those described in the vegetation section found earlier in this chapter, and presumably the results would be similarly positive. This premise was highlighted in a review article on the potential effectiveness of phytoremediation in riparian areas, where Karthikeyan et al. (2004) drew on similarities between streamside areas and other locations where phytoremediation has been effectively employed to treat pesticide-contaminated soil and water. Similarly, another review paper summarized a range of studies that investigated phytoremediation in aquatic settings, addressing plant species such as cattail (*Typha* spp.) and Cutgrass *Leersia oryzoides* which can be found along the riparian-aquatic ecosystem transition (Moore et al. 2011). A study directly examining the use of phytoremediation in riparian areas found that Tussock Sedge *Carex stricta*, Switchgrass *Panicum virgatum* and Gamagrass *Tripsacum dactyloides* led to approximately 70% reduction in total petroleum hydrocarbons under controlled riparian conditions, while there was only about 20% reduction associated with a Narrowleaf Willow *Salix exigua* and poplar

(*Populus* spp.) (Euliss 2008). Following the same procedure in an uncontrolled riparian field site did not reproduce these promising results, but the authors presumed there was a continuous pollutant source re-contaminating the site during the study. A field study examining the phytoremediation potential of willows (*Salix* spp.) in riparian areas yielded a 49% decrease in PCB concentrations before contaminated groundwater reached the stream margin (Skłodowski et al. 2014). Although there is not enough information available in the literature to provide design guidelines for implementing a phytoremediation-based system, there is promise in this approach to attenuating organic contaminants in riparian areas and further research should be encouraged.

Mycoremediation, the degradation of contaminants by fungi, is a type of bioremediation that occurs in soils. This process likely takes place in riparian soils with high organic matter content where lignin-degrading fungi (more commonly known as wood-decay fungi, a class that includes brown rot, soft rot, and white rot) exist. These microorganisms possess the ability to breakdown organic contaminants, particularly PAHs, through the release of a variety of oxidizing enzymes (Haritash and Kaushik 2001). Research on promoting lignin-degrading fungi as a remediation agent started to appear in

the literature in the 1990s, but did not receive much attention until after the turn of the century (Lamar et al. 1993; Boonchan et al. 2000; Canet et al. 2001). Results vary considerably, but it is not uncommon to observe 50% to 90% reductions in organic pollutants resulting from mycoremediation-mediated degradation (Lamar et al. 1993; Boonchan et al. 2000; Haritash and Kaushik 2001). Although this degradation process is mentioned here to highlight the mechanisms affecting organic pollutants in riparian soils, it has been suggested that mycoremediation could potentially be capitalized on as an engineered mitigation technique in riparian areas, but more research is needed (Jones 2009).

Despite the large body of knowledge that has been developed, the mechanistic understanding of pesticide transport through riparian areas is incomplete. The following summarizes our understanding of the typical transport pathways of a pesticide; this is essential information to consider when determining appropriate riparian widths for attenuation. Pesticide migration from terrestrial sources to stream channels can follow a number of different pathways. The specific transport mechanism governing pesticide movement from uplands through riparian areas and into surface waters is highly

correlated to the type of pesticide in question. Surface runoff can carry pesticides off fields as either dissolved forms or attached to eroded soil particles. Leaching of compounds entails their vertical movement through the soil, after which they can either move toward the stream through the unsaturated zone or via groundwater flow. The chemicals that move in the dissolved form tend to be those that exhibit low to moderate sorption properties, as compounds that possess lower partition coefficients are prone to leach into the soil profile. Leaching is further promoted in regions with high precipitation and in soils that are coarse-textured, contain a low percentage of organic matter, or demonstrate a high degree of macropore flow. Pesticides that predominantly follow sediment-facilitated transport are generally those that display a strong affinity to soil particles (i.e.,  $K_{OC} > 1,000$  L/kg).

While the literature lacks information on the potential attenuation in riparian areas for most organic pollutants, there are a substantial number of papers on the movement of pesticides through buffer strips. A number of review papers evaluate pesticide attenuation in riparian areas, with a particular emphasis on managed vegetative filter strips (Krutz et al. 2005; Lacas et al.

2005; Reichenberger et al. 2007). Due to the complexity of the attenuation mechanisms involved, the removal rates within buffers vary considerably between disparate compounds, as well as when comparing the removal rates of the same pesticide at different locations. Depending on the conditions, mass removal rates for some pesticides can be negligible while others can reach 100%. Research has shown that herbicide type and filter strip width are primary factors affecting herbicide retention in riparian areas, while antecedent moisture conditions exert an additional effect wherein pesticide attenuation is generally negatively correlated with soil moisture. The type of vegetation appears to have negligible impact on pesticide retention, with studies showing that a grass-shrub-tree mixture exhibited comparable mitigation as grass only. Interestingly, one study found that pesticide mitigation was greater at higher incoming concentrations, which was attributed to better sorption to soil and plant material (Misra et al. 1996).

Due to confounding and often conflicting results, after 35 years of research, there remains a lack of consensus on the minimum filter strip widths needed for effective pesticide removal from surface and surface overland flow. The NRCS recommends a standard width of 49 ft (15 m) with the aim of achieving 50% effectiveness, but there is not much evidence to support this guidance (NRCS 2000). Another general recommendation for diffuse runoff suggests riparian widths of 33 and 66 ft (10 and 20 m) for hillslopes of under and over 328 ft (100 m) in length, respectively (Lacas et al. 2005). However, because this recommendation is based on only one experimental study, it may not be applicable to other locations with different hydrological, soil, and vegetative conditions.

## Pesticide Spray Drift

Pesticide spray drift, the aerial transport of pesticide droplets off target areas during spray application, presents another pathway by which these chemicals

can enter aquatic ecosystems. Unlike hydrological transport, pesticide physicochemical properties play a negligible role in aerial transport (although formulation does act as an influencing factor). Weather conditions (e.g., wind speed, temperature, and humidity), equipment type, application practices, and target crop all affect aerial transport. There is a better understanding of pesticide aerial drift to streams than that of hydrological pathways, either as a result of occurring in a less complex matrix, or as Reichenberger et al. (2007) asserts, due to aerial drift receiving more regulatory scrutiny.

Management of riparian areas can significantly reduce pesticide spray drift in many cases, particularly when conducted in conjunction with proper application practices. However, in their review of mitigation via windbreaks, Ucar and Hall (2001) found no general consensus on optimum riparian buffer widths to protect water quality. Their review reports that research has yielded buffer width recommendations that range from 20 to 150 ft (6 to 45 m) for ground application and 80 to over 4,000 ft (25 to over 1,200 m) for aerial application. Despite this lack of harmony in recommendations, individual cases have yielded positive results. Analysis of a forested riparian area in British Columbia found that a 25 ft (7.6 m) buffer limited the amount of herbicide reaching the stream to less than 0.1% of the aerial application (Feng et al. 1990). In an agricultural setting, a simple 10 ft (3 m) no-spray buffer reduced herbicide drift deposition to adjacent surface waters by 95%, and no measurable drift reached the stream at a width of 20 ft (6 m) as long as the wind-speed was below 15 mph (25 kph) in the direction towards the buffer (De Snoo and De Wit 1998). Many factors contribute to the effectiveness in reducing pesticide drift to acceptable levels. While wind-speed and application method exert significant impacts, vegetation height, density, orientation, and species composition all play pivotal roles. For instance, Ucar and Hall (2001) suggest that, in general, evergreen species display capture efficiencies 2 to 4 times greater than deciduous trees.

## 5.4.5. Pathogens

Pathogens impair more waterbodies in Washington than any other contaminant (USEPA 2015). Fecal contamination of surface waters can lead to the introduction of various pathogenic bacteria, fungi, viruses, protozoans, and worms that infect the gastrointestinal tract and present a health risk to both humans and wildlife. Common infections related to fecal pollution result from the presence of pathogenic bacteria such as *Escherichia coli* (*E. coli*), *Salmonella* spp. and *Vibrio* spp. or viruses such as Rotavirus. Primary pathogenic protozoans of concern include *Cryptosporidium parvum* and *Giardia lamblia*, which are able to form oocysts (protective spores) that allow them to survive outside of a host for long periods. Helminths represent a general class of parasitic worms, including flatworms and roundworms, which can act as intestinal parasites. The myriad pathogens that can be found in riverine systems following fecal contamination makes it impractical to list them here, but it is important to understand the four different pathogenic categories that can be conveyed to people through surface water contact or ingestion.

Pathogens comprise a diverse range of microorganisms that are typically found in low concentrations, making it impractical to test for specific pathogens when conducting water quality assessments. As an alternative, “pathogen indicator organisms” are used as a proxy to assess the potential presence of pathogens in a water sample. Commonly employed pathogen indicators include total coliforms, fecal coliforms, and *E. coli*. Total coliforms comprise a group of five genera of bacteria that easily can be analytically differentiated from other microorganisms, and while some occur naturally in soils, many are found in the gastrointestinal tract of warm-blooded animals and can serve as a general marker for fecal contamination. Fecal coliforms represent a sub-group of total coliforms that more specifically reside in the intestines of warm-blooded

animals, making them a more accurate indication of the presence of fecal material in water. Washington water quality standards use fecal coliforms as indicator organisms to determine water quality impairment. *E. coli*, a species in the fecal coliform group, is a dominant inhabitant in the digestive tract and is generally considered the best indicator of fecal pollution of the three. As *E. coli* are indigenous enteric bacteria, they are not in themselves pathogenic although some strains are (e.g., *E. coli* O157:57). Although most of these indicator organisms are not pathogenic, it is common to refer to them as pathogens when discussing water quality (shortening the phrase “pathogens and pathogenic indicator organisms”), and while technically inaccurate, we will use that term in this section. We use the term in a way that should allow the reader to differentiate between whether we are referencing pathogens specifically or the broader group that includes pathogen indicator organisms.

As the pathogens in question are enteric, they are introduced into the environment through the feces of warm-blooded animals. Principal pathways for pathogens entering aquatic ecosystems are through direct defecation by livestock, wildlife, and pets in the riparian area and via overland flow carrying fecal material from upland pastures, animal feeding operations, fields that have received land-applied manures, or seepage from septic or sewage systems. Feces from domesticated dogs can be a predominant pathogen source in urban areas, as a study in Seattle attributed 30% of the fecal contamination to canines (Tobiason et al. 2002). Hobby farms also present an often-overlooked source adversely affecting water quality, and this has been shown to be an issue in Washington (Morace and McKenzie 2002).

The fate of pathogenic microorganisms in the environment is still not well understood in general and much uncertainty remains in the context of riparian areas. While many of the pathogens that can contaminate surface waters are obligate parasites,

some can persist outside of an animal's gastrointestinal tract in the environment. The length of time these microorganisms can survive under different conditions is a current topic of debate in the research community. The general assumption in the past was that these enteric organisms were not able to persist in the environment for more than a few days following excretion in feces. However, more recent research indicates that bacterial pathogens can survive for much longer periods, and it is generally recognized that persistence in the environment for two to three months is not uncommon. Longer survival rates are possible given the correct conditions, as demonstrated in a laboratory study where *E. coli* O157:H7 persisted for over 190 days in manure-amended soils (Jiang et al. 2002). General factors that influence the survival of pathogenic bacteria that enter riparian areas include soil moisture, temperature, pH, sunlight, nutrient availability, soil texture, and biological interactions. Moist, nutrient-laden, shady conditions such as those often found in riparian areas theoretically would provide an environment in which pathogens could survive longer, potentially being picked up by overland flow and introduced to adjacent stream channels.

Although considerable research has been conducted through the years on bacterial movement through environmental systems, research is in the nascent stages of examining the transport and fate of pathogens across the landscape and in riparian areas. Unc and Goss (2004) offer a concise review on the transport of bacteria from manure in relation to protecting water resources, and although the material presented does not focus on streamside areas it does provide fundamental information on the mechanisms involved in pathogen transport. The body of research that has examined pathogen attenuation in riparian areas is small although expanding, and almost all findings are related to vegetative filter strips and do not consider natural riparian ecosystems.

The capacity of vegetative filter strips to remove pathogens is not well established and research results

have demonstrated that these systems exhibit great variability in their effectiveness in removing pathogens. A number of studies have shown that filter strips impart no significant influence on pathogen and pathogenic indicator organism concentrations moving toward a stream channel (Walker et al. 1990; Schellinger and Clausen 1992; Chaubey et al. 1995; Coyne et al. 1995; Entry et al. 2000). Contradictory findings have been generated by other studies that promote the idea that well maintained filter strips can serve as an effective BMP to prevent pathogens from reaching surface waterbodies (Coyne et al. 1998; Fajardo et al. 2001; Tate et al. 2006).

Inconsistent findings result from a number of factors. Soil infiltration, antecedent soil moisture conditions prior to a rain event, vegetation status, topography, and rainfall intensity and duration all have been identified as key controlling variables (Muñoz-Carpena et al. 1999; Guber et al. 2009). Each of these parameters relates to the concept that pathogens being carried in overland flow are removed by their infiltration into the soil where they typically are filtered or adsorbed to soil particles. High intensity rain events and concentrated flow can significantly reduce pathogen removal efficacy below that which would occur under low-flow conditions (Fox et al. 2011b). Vegetative filter strip width plays a significant role in pollutant removal, where a linear

---

*Although considerable research has been conducted on bacterial movement through environmental systems, research is in the nascent stages of examining the transport and fate of pathogens across the landscape and in riparian areas.*

decrease in pathogenic bacteria has been consistently observed with increasing buffer width (Young et al. 1980). However, a potential exists for trapped pathogens to later be remobilized in subsequent runoff events. Higher concentrations of pathogens have been recorded in runoff during a second runoff event, which suggests that filter strips could become indirect sources of pathogens under some conditions (Collins et al. 2004).

## 5.5. Effect of Riparian Buffer Width on Pollutant Removal

The pollutant removal function of riparian areas has been studied for at least 40 years (e.g., Doyle et al. 1975), and the enormous quantity of scientific research over the past four decades has motivated numerous reviews of the scientific literature (Norris 1993; Osborne and Kovacic 1993; Barling and Moore 1994; Vought et al. 1995; Fennessy and Cronk 1997; Lyons et al. 2000; Dosskey 2001; Hickey and Doran 2004; Lacas et al. 2005; Krutz et al. 2005; Polyakov et al. 2005; Hoffman et al. 2009; Dosskey et al. 2010). Despite the large quantity of research and number of literature reviews, no widely accepted recommendations have emerged on minimum buffer widths needed to protect water quality. The lack of agreement amongst scientists is due, in part, to the surprising complexity of the mechanisms that remove pollutants from surface and subsurface flows in riparian areas, to the variety of research methods used to study pollutant removal by riparian buffers, and to the many different environmental conditions at research sites.

The quantitative metric of pollutant removal by riparian areas is referred to as removal efficacy, removal efficiency, or percent removal. These measures are usually defined as:

$$E_R = \frac{m_{in} - m_{out}}{m_{in}} \times 100 \quad (1)$$

where  $m_{in}$  and  $m_{out}$  are the mass or concentration of the pollutant entering and exiting a riparian buffer, respectively. The primary question addressed by nearly all research on the pollutant removal function of riparian areas, and by nearly all literature reviews, is how does riparian buffer width affect removal efficacy? The main answers are: 1) removal efficacy increases as buffer width increases, 2) topographic slope and vegetation type strongly affect removal efficacy, and 3) the relationship between removal efficacy and buffer width is highly variable.

In addition to the many literature reviews cited above, several statistical meta-analyses of research results (Mayer et al. 2007; Liu et al. 2008; Yuan et al. 2009; Zhang et al. 2010; Sweeney and Newbold 2014) provide synoptic perspectives on what is currently known about the relationship between buffer width and removal efficacy (Table 5.1). Research results from throughout the world were collected by all five meta-analyses, but the majority were from North America. The remainder of this section discusses the findings of those meta-analyses.

Four meta-analyses looked at the results of research on sediment removal. The meta-analyses found that buffer width alone explained 28% to 37% of the variance in sediment removal results. Models for removal efficacy versus buffer width predicted a wide range of buffer widths necessary for 90% efficacy: 33, 39, 75, and 170 ft (10, 12, 23, and 52 m) (Figure 5.2). Three of the meta-analyses found that adding slope as an independent variable significantly improved the fit of their models to the data. Two meta-analyses (Liu et al. 2008; Zhang et al. 2010) using the same studies but different modeling assumptions, found that optimum slope for sediment removal was about 10%. In other words, removal efficacy increased as slope increased from 1 to 10%, but then removal efficacy decreased as slope increased above 10%. However, extrapolating these findings to other locations should be done cautiously as this relationship may not hold under many conditions. Zhang et al. (2010) found that buffer width, slope,

and vegetation type together could explain 65% of the variance in sediment removal results. Curiously, they also found that buffers composed of grasses only or trees only were more efficacious at removing sediment than buffers composed of both grasses and trees (Figure 5.4).

Three separate meta-analyses looked at the results of research on nitrogen removal. The meta-analyses of Zhang et al. (2010) and Mayer et al. (2007) produced very different relationships for removal efficacy versus buffer width. Zhang et al. (2010) found that buffer width alone explained 44% of the variance in nitrogen removal results, but Mayer et al. (2007) found buffer width alone explained only 9%. Furthermore, Zhang et al. (2010) predicted that buffer widths of 80 ft (24 m) are necessary for 90% removal efficacy, while Mayer et al. (2007) predicted buffer widths of 436 ft (133 m) for the same efficacy (Figure 5.3). Separate models by Mayer et al. (2007) for surface and subsurface flows found a significant relationship (assuming  $\alpha = 0.05$ ) between buffer width and removal efficacy for surface flows ( $R^2 = 0.21$ ,  $P = 0.03$ ) but not for subsurface flows ( $R^2 = 0.02$ ,  $P = 0.3$ ). Despite this result, Mayer et al. (2007) found that riparian buffers were more efficacious in removing nitrogen from subsurface waters than from surface waters. Mayer et al. (2007) found no significant relationship between nitrogen removal and buffer vegetation type but their collection of studies did show that buffers lacking trees (herbaceous cover only) were the least efficacious at removing nitrogen.

Zhang et al. (2010) found a relationship between vegetation type and nitrogen removal and that buffers composed of trees remove more nitrogen than buffers completely or partially composed of grasses. Zhang et al.'s model that included buffer width and vegetation type explained 49% of the variance in nitrogen removal results.

Comparing regression models for sediment and nitrogen removal (Figures 5.2 and 5.3) illustrates three important points regarding the pollutant removal function of riparian areas. First, the magnitude of removal efficacy for different pollutants can be very different. According to the models, 80% of sediment was removed at roughly 50 to 65 ft (15 to 20 m), but 80% removal of nitrogen may require buffer widths two to four times wider. Second, the variability of removal efficacy for various pollutants can be significantly different. The regression models for nitrogen removal show much more variation than the models for sediment removal. The wider variation is due, in part, to the greater complexity of the chemical and biological processes affecting nitrogen removal compared to the simpler physical processes affecting sediment removal. Hence, our ability to predict removal efficacy and our certainty about water quality protection can be very different for different pollutants. Third, for all pollutants the relationship between buffer width and removal efficacy follows a law of diminishing marginal returns. That is, the marginal (or incremental) amount of pollutant removal decreases as buffer width increases.

Zhang et al. (2010) also conducted meta-analysis for phosphorus and pesticides. Buffer width alone explained 35% of the variance in phosphorus removal results (Figure 5.5), and with the addition of vegetation as an independent variable, the model explained 47% of the variance. The buffer-width-only model predicts 89% phosphorus removal with a buffer 98 ft (30 m) wide.<sup>7</sup> Buffers with trees were found to remove more phosphorus than buffers completely or partially composed of grasses. The pesticide meta-analysis included 11 chemicals (norflurazon, fluometuron, lindane, deisopropylatrazine, deethylatrazine, atrazine, permethrin, bromide, terbuthylazine, metolachlor, isoproturon). Buffer width alone explained 60% of the variance in pesticide removal results, and vegetation was found to be an insignificant predictor variable. The model predicts 92% pesticide removal with a buffer 65 ft (20 m) wide.

<sup>7</sup> Because Zhang et al. (2010) assumed an asymptotic equation for their regression, the phosphorus model was invalid for efficacies greater than 89.5%.

Using data provided by Zhang et al. (2010), we calculated prediction intervals for their phosphorus model.<sup>8</sup> A prediction interval describes the precision of a model's predictions and the interval's width is a metric of uncertainty. For a buffer 33 ft (10 m) wide, the width of the 90% prediction interval is 64%. Therefore, while the model predicts that a 33 ft (10 m) buffer will provide an average removal efficacy of 70%, the actual removal

efficacy obtained by another study on phosphorus removal (i.e., one which was not included in the meta-analysis) is likely to be somewhere between 38 and 100% (70% ± 32%). The low precision of the model's prediction interval is related to the unexplained variance that could be attributed to other variables not included in the regression, such as site slope and various soil properties.

**Table 5.1. Descriptive information for functional relationships on sediment removal shown in Figure 5.2 and nitrogen removal shown in Figure 5.3. Reference numbers 1 through 4 correspond to numbers in Figures 5.2 and 5.3. In the equations,  $E_R$  is the removal efficacy,  $width$  is riparian buffer width, and  $a$ ,  $b$ ,  $c$ ,  $d$ , and  $k_{50}$  are parameters determined through linear or nonlinear regression.**

| Pollutant | Meta-analysis                   | Form of equation                                               | Model                                                                                                               | $N^{***}$ | $R^2$ | $P$ value |

\* Signifies that  $P$  value was not reported in cited study.

\*\* Nearly all the studies included by Liu et al. (2008) and Zhang et al. (2010) in their meta-analyses were the same studies.

\*\*\*  $N$  signifies number of studies in meta-analysis.

† Studies for subsurface nitrate removal only.

‡  $q$  represents subsurface water flux. 58 and 115 L/m/day are median and mean subsurface water fluxes for studies collected by Sweeney and Newbold (2014).

<sup>8</sup> A prediction interval is a range that is likely to contain the dependent response value ( $Y_i$ ) for a new observation ( $X_i$ ). A prediction interval assumes that the new observation is taken from the same population used to create the regression equation.

Figure 5.2. Relationships between sediment removal efficacy and riparian buffer width developed by four separate meta-analyses. Numbers in parentheses refer to different meta-analyses. See descriptive information in Table 5.1.

Figure 5.3. Relationships between nitrogen removal efficacy and riparian buffer width developed by three separate meta-analyses. Numbers in parentheses refer to different meta-analyses. See descriptive information in Table 5.1.

Figure 5.4. A result from meta-analysis of Zhang et al. (2010). Sediment removal efficacy as a function of buffer width, site slope, and buffer vegetation ( $N = 81$ ,  $R^2 = 0.65$ ,  $P < 0.001$ ).

Figure 5.5. Meta-analysis of Zhang et al. (2010). Results of nonlinear regression for phosphorus removal efficacy as a function of buffer width ( $N = 52$ ,  $R^2 = 0.35$ ,  $P < 0.0001$ ) with 90% and 95% prediction intervals.

# 5.6. Reanalysis of Meta-Analyses

A major assumption made by each of the meta-analyses was the type of equation that would result in the best fit to their data. Zhang et al. (2010), for instance, chose to use a nonlinear asymptotic equation of the form:

$$E_R = a \left( 1 - e^{b \times width} \right) \tag{2}$$

where  $E_R$  is removal efficacy, *width* refers to buffer width, and *a* and *b* are coefficients determined through nonlinear regression. In equation (2), *a* determines the maximum removal efficacy possible (i.e., it is an asymptote). Zhang et al. (2010) conducted their regression such that *a* could be less than 100%. For sediment, pesticide, nitrogen, and phosphorus pollutants, *a* equaled 91, 93, 92, and 89.5 percent, respectively. Hence, we could not determine buffer widths needed for removal efficacies greater than these values of *a* in their models. This limitation was particularly problematic for pesticides and phosphorus because Zhang et al. (2010) was the only meta-analysis for those pollutants.

To determine buffer widths needed for higher removal efficacies (90, 95, 99%), we reanalyzed Zhang et al.'s data with a nonlinear equation of the form:

$$E_R = a + b \ln(width) \tag{3}$$

This form of model is the same used by Liu et al. (2008) and Yuan et al. (2009).<sup>1</sup> We performed linear regression in R (RCT 2013) using the `lm` function, but first we established that we could obtain the same regression results (same values for *a* and *b*) as Zhang et al. (2010) using equation (2). This confirmed that the data we downloaded from the internet were the same data used by Zhang et al. (2010). We then redid the regression

using equation (3). With the exception of sediment, the resulting models fit the data as well or better than the original models of Zhang et al. (2010) (Table 5.2). Graphical comparisons of our results and those of Zhang et al. (2010) are presented in Figure 5.6.

Table 5.2. Comparison of  $R^2$  values for Zhang et al.'s (2010) model and our reanalysis using equation (3). *N* is the number of studies included in the meta-analysis.

| Pollutant  | <i>N</i> | $R^2$               |            |
|------------|----------|---------------------|------------|
|            |          | Zhang et al. (2010) | Reanalysis |
| Sediment   | 81       | 0.37                | 0.31       |
| Nitrogen   | 61       | 0.44                | 0.44       |
| Phosphorus | 52       | 0.35                | 0.39       |
| Pesticides | 49       | 0.60                | 0.61       |

Juvenile fish find shelter in a root wad/Terra Hegy, WDFW

<sup>1</sup> Xuyang Zhang, the lead author of Zhang et al. (2010), also recommended that we use equation (3) because equation (2) cannot model 100% removal efficacy (X. Zhang, California Department of Pesticide Regulation, personal communication, May 14, 2019).

Figure 5.6. Relationship between removal efficacy and buffer width. Data from meta-analysis of Zhang et al. (2010) but reanalyzed using different form of nonlinear model. Line colors: blue: best fit model, red: 90% prediction interval, purple dashed: original model of Zhang et al. (2010), black dashed: 100% removal efficacy

We also reanalyzed two other meta-analyses – Mayer et al. (2007), and Sweeney and Newbold (2014) – for two reasons. The first reason was consistency across meta-analyses. The meta-analyses gave different answers for the relationship between removal efficacy and buffer width. For example, Zhang et al. (2010) predicted that buffer widths of 80 ft (24 m) are necessary for 90% removal efficacy of nitrogen, while Mayer et al. (2007) predicted buffer widths of 436 ft (133 m) for the same efficacy. Part of this discrepancy may be due to the type of equations adopted for their nonlinear or linear regressions, so we redid both meta-analyses using the same equation. Second, as noted earlier, a major assumption made by each of the meta-analyses was the type of equation that would result in the best fit to their data. We tested that assumption, and found that equation (3) often resulted in a better fit.

Mayer at al. (2007) chose to use a power function of the form:<sup>2</sup>

$$E_R = a \text{ width}^b \tag{4}$$

where *a* and *b* are coefficients determined through linear regression. We reanalyzed their data using equation (3). The resulting models fit the data as well or better than the original models of Mayer et al. (2007) (Table 5.3, Figure 5.7). For subsurface flow, the relationship between removal efficacy and buffer width was statistically insignificant (*P* = 0.30) and *R*<sup>2</sup> was only 0.02 for both their model and ours. We also note that both models produce somewhat absurd results – 60% of subsurface nitrogen can be removed with buffers only 2 ft wide but 90% removal requires buffers over 1200 ft wide. Hence, we will use neither model in further discussions of sub-surface nitrogen removal. For surface flow, the reanalysis resulted in a slightly better fit to the data – *R*<sup>2</sup> improved from 0.21 to 0.28.

We did not reanalyze the meta-analysis that Sweeny and Newbold (2014) did on studies of nitrogen removal from groundwater. While Sweeney and Newbold (2014)

Table 5.3. Comparison of *R*<sup>2</sup> values for Mayer et al.'s (2007) model and our reanalysis using equation (3). *N* is the number of studies included in the meta-analysis.

|                      |          | Mayer et al. (2007)   |          | Reanalysis            |          |
|----------------------|----------|-----------------------|----------|-----------------------|----------|
| Model                | <i>N</i> | <i>R</i> <sup>2</sup> | <i>P</i> | <i>R</i> <sup>2</sup> | <i>P</i> |
| nitrogen, surface    | 23       | 0.21                  | 0.03     | 0.28                  | 0.009    |
| nitrogen, subsurface | 65       | 0.02                  | 0.30     | 0.02                  | 0.30     |

found a significant statistical relationship between nitrogen removal from subsurface flow and buffer width, other studies suggest the buffer width has little or no effect on nitrogen removal from subsurface flow (Hruby 2013, pp. 10-11).

For sediment removal, Sweeney and Newbold (2014) chose an equation of the form:

$$E_R = \frac{\text{width}}{k_{50} + \text{width}} \tag{5}$$

where *k*<sub>50</sub> equals the buffer width expected to remove 50% of sediments and it is determined through nonlinear regression. We reanalyzed their data using equation (3). The resulting model fits the data better than the original model of Sweeney and Newbold (2007). Their *R*<sup>2</sup> was 0.28 and the new *R*<sup>2</sup> is 0.33 (Figure 5.7).

Table 5.4 shows the buffer width needed to achieve desired levels of pollutant removal as predicted by meta-analyses and our reanalyses of meta-analyses. We combined predictions from multiple meta-analyses using a weighted average with the weights being the products of *N* and *R*<sup>2</sup>. Note that values in Table 5.4 are predicted averages for removal efficacy. The actual efficacy realized by implementing a particular buffer width could be much better or worse. The amount of uncertainty in the realized removal efficacy is depicted by prediction intervals in Figures 5.6 and 5.7. The

<sup>2</sup> The equation *E<sub>R</sub>* = *a width*<sup>*b*</sup> can be transformed to the equation *ln(E<sub>R</sub>)* = *a'* + *b ln(width)*, which is similar in structure to equation (3) and results in a similar fit to the data. Equation (3) was also the form used by Mayer et al. (2006).

Riparian areas capture pollutants/Marlin Greene, One Earth Images

reanalyzed meta-analysis of Zhang et al. (2010), for example, predicts that 90% of sediment can be removed with a 42 ft (13 m) wide buffer, however, according to the prediction interval, the buffer width needed for 90% removal could be as narrow as 8 ft (2.4 m) or as wide as 225 ft (69 m). Better models that include other independent variables, such as slope and vegetation

(e.g., Zhang et al. 2010), will reduce this uncertainty, but there is a trade-off. The application of more complicated models leads to more complicated management. If, for example, managers adopted a model that includes vegetation type or vegetation structure, then, in addition to buffer width, they must also manage the condition of vegetation within the buffer.

Figure 5.7. Relationship between removal efficacy and buffer width. Study results from meta-analyses reanalyzed using different form of equation in a linear regression. Left: nitrogen study results from Mayer et al. (2007). Right: sediment study results from Sweeney and Newbold (2014). Line colors: blue: best fit model, red: 90% prediction interval, purple dashed: original models from meta-analyses, black dashed: 100% removal efficacy.

Table 5.4. Buffer width in feet needed to achieve desired levels of pollutant removal from run-off. Buffer width calculated with model and/or data from the cited literature. Models had only one predictor variable, which was buffer width. Mean buffer width for sediment and nitrogen removal are weighted averages of widths determined by each meta-analysis. Weights were the product of *N* and *R*<sup>2</sup>.

| Average Removal Efficacy (%) |                                               |          |                       | 80                | 90  | 95  | 99  |

\* Nearly all the studies included by Liu et al. (2008) and Zhang et al. (2010) were the same studies.

‡ The parameter *q*, which represents subsurface water flux, was set to 58, which is the median value for 30 studies analyzed by Sweeney and Newbold (2014).

## 5.7. Conclusions

There is a consensus in the scientific literature that riparian areas reduce the flow of pollutants to aquatic ecosystems, and that pollutant removal functions are contingent on complex interactions between hydrology, soil, and vegetation, and are influenced by many other factors as well. Because hydrology, soil, vegetation and other factors exhibit high spatial and temporal variability, the efficacy of pollutant removal functions provided by riparian areas differs substantially among sites, as well as within sites. Determining the potential for riparian areas to protect water quality is further complicated by the disparate behavior of different contaminant types in the environment. While space limitations required

us to simplify this review of the scientific literature regarding pollutant removal functions of riparian areas, we provided the basic information needed for understanding these important ecological functions.

Our review of the literature presents a substantial body of scientific research with which to develop strategies, plans, or policies regarding the pollutant removal functions of riparian areas. The central problem faced by resource managers is determining the adequate riparian buffer width, composition, and structure to protect water quality with high degrees of efficacy, efficiency, and certainty. Riparian function is often simplistically characterized by buffer width and vegetation type, but these parameters only partially explain the effects that riparian areas have on pollutant removal. The current conservation paradigm remains strongly tied to the

premise that wider riparian areas are the only way to increase pollutant removal efficacy, but this is not always the case; other site-specific factors, such as conditions within the buffer, also exert a significant influence on removal efficacy. Therefore, consideration of the entire system (i.e., riparian area, uplands, vegetation, soils, ground and surface water pathways, topography, type of pollutant, etc.) is essential to developing cost-effective pollutant removal. In theory, buffer width and vegetation could be optimized for site conditions such that water quality is protected while minimizing economic costs for landowners.

Despite the many scientific uncertainties, management decisions must be made. Management decisions regarding pollutant removal by riparian buffers should be informed by science, but determining the “right” buffer width for pollutant removal cannot be purely scientific. Determining the “right” buffer width begins with choosing a desired removal efficacy, and that choice is normative. That is, the desired removal efficacy is a social choice influenced by cultural values, economic costs, and risk tolerance. Choosing a desired removal efficacy and determining the “right” buffer requires:

- 1) factual information regarding the anticipated impacts or outcomes of policy options (i.e., science);
- 2) an understanding of stakeholders’ priorities and preferences (i.e., values); and
- 3) a process for using science and values to explore tradeoffs amongst policy options (Wilhere and Quinn 2018).

# Chapter 6. Nutrient Dynamics in Riparian Ecosystems

*By: Paul M. Mayer, Jana E. Compton, and George F. Wilhere*

## 6.1. Introduction

**R**iparian ecosystems play a vital role in the dynamics of nutrients within watersheds, especially for the three primary macronutrients carbon (C), nitrogen (N), and phosphorus (P). Because they are positioned at the interface between the stream and upland areas, riparian ecosystems mediate the movement of materials and energy between land and water. Riparian areas can be sources or sinks of energy, water, nutrients, organic matter, and organisms within a watershed. Organic matter from riparian areas, an important source of energy and nutrients, makes its way into streams via plant litterfall, or through transport by water, wind, or animals. Organic matter in streams provides habitat and food for microbes, insects, fish, amphibians, birds, and other organisms, and decomposes to release plant-available inorganic nutrients like ammonium, nitrate, and phosphate. Riparian areas also store energy and nutrients from organic matter coming from upland and instream sources through biotic uptake, sorption and exchange, and slowing or trapping particles. Riparian areas also are sites with high rates of nutrient transformation, including conversion of inorganic nitrogen into the gases  $N_2$  or  $N_2O$  via denitrification. Riparian ecosystems are influenced by upland activities that supply nutrients that follow flow paths through these ecosystems, eventually reaching streams via surface and subsurface flows. Age, vegetation composition, topography, soil type, and condition of the riparian ecosystem all factor into the fate and transport of nutrients. In addition, the position

in the drainage network and connectivity of the riparian area, along with disturbance and management history, affect nutrient processing rates.

Nutrients and the hydrological and biogeochemical processes that dictate their transport and fate are the subject of much current research in riparian ecology (Mayer et al. 2010a, 2014) because of their critical importance for growth and maintenance of life in the riparian ecosystem and the subsequent effects on stream biota and water quality. Although many micro- and macro-nutrients cycle through riparian areas, this chapter addresses only the three primary macronutrients C, N, and P.

Streams in the Pacific Coastal Ecoregion of Washington State are generally oligotrophic, well shaded, and sensitive to nutrient enrichment (Welch et al. 1998). When more N and P enters a riparian ecosystem than can be immediately utilized or stored, degradation of aquatic habitat conditions can occur and negative consequences within or beyond the riparian ecosystem may result. Excess N and P input to streams and estuaries may lead to harmful algal blooms, hypoxia, fish kills, and contamination of drinking water supplies. Although stream nutrient concerns have a somewhat lower profile in the Pacific Northwest (PNW) relative to other areas of the US, such as the Chesapeake Bay or Great Lakes watersheds, approximately 20% of assessed rivers and 8% of assessed lakes in Washington are regarded by the state as having impaired conditions related to an overabundance of nutrients (USEPA ATTAINS database).

Here, we describe nutrient cycles in riparian areas in the PNW, focusing on C, N, and P from natural and anthropogenic sources. Other nutrients, such as calcium, sulfur, or molybdenum, are not as widely studied but have been shown to be important in areas of the PNW for forest growth or other ecosystem processes (Silvester 1989; Chappell et al. 1991; Perakis et al. 2006). When possible, we discuss implications of common land management activities on nutrient dynamics by contrasting disturbed versus undisturbed riparian ecosystems. We also discuss new information gained from recent stable isotope studies and meta-analyses of riparian nutrient removal that have greatly improved our understanding of the permanence and effectiveness of nutrient removal processes in PNW riparian ecosystems.

## 6.1.1. Nutrient Dynamics in the Pacific Northwest

Figure 6.1 illustrates processes occurring in a largely undisturbed PNW forested riparian ecosystem and associated stream and upland. Water traveling through the riparian area (surface and subsurface flow) is the main transport mechanism for dissolved C, N, and P. These nutrients can be taken up directly by primary producers and decomposers, passively transported to groundwater or the hyporheic zone, or carried to surface waters via subsurface, overland, or channelized flow. The hydrologic regime dictates the timing and magnitude of nutrient movement into aquatic systems, and can create instream pulses of C, N, and P both in particulate and dissolved form (Kaushal et al. 2010).

Figure 6.1. Nutrient cycle of an undisturbed PNW forested riparian ecosystem and connected stream and upland forest. Modified from Moyle et al. (2009). DIP = dissolved inorganic phosphorus; DOC, DON, DOP = dissolved organic carbon, nitrogen and phosphorus, respectively.

*Most streams in the Pacific Northwest are nutrient-poor ecosystems/Ned Pittman, WDFW*

Soil compaction and impervious surfaces typically reduce retention capacity of nutrients in space and time by preventing infiltration and thereby limit the interaction of nutrients with soils, roots, and soil biota. Riparian ecosystems exhibit a continuum of physical characteristics which have implications for nutrient dynamics. Riparian ecosystems along low-order streams, for example, are often narrower and steeper than those along mainstem rivers with wide, level floodplains. Consequently, surface and subsurface hydrological regimes controlling biogeochemical processes in riparian areas also differ along a continuum. Along small, steep forested streams, the water table is usually low and aerobic processes dominate, whereas level areas adjacent to larger rivers may provide water table conditions favoring anaerobic processes that reduce N via denitrification, a microbial transformation of dissolved nitrate N to gaseous molecular N (Burt et al. 2002; Hefting et al. 2004). The hyporheic zone is an area beneath the stream and riparian area where surface water and ground water continually interact. This zone can have a large influence on chemical characteristics of the surface water

and, therefore, plays a role in determining biological attributes of streams (Wondzell et al. 2011).

As nutrient molecules move downstream, they may be taken up by algae and microbes living on rocks and wood in the channel in slick mats called biofilms (Cardinale et al. 2002). The polysaccharide layers of biofilms are sites of active nutrient turnover where microscopic algae, fungi, and bacteria consume N and P, die and release nutrients that then move further downstream. Microbial communities may be consumed by grazers such as larval aquatic insects or snails, which in turn may be consumed by larger predators such as fishes or birds. As prey and predators are consumed or die, they release nutrients to the aquatic and terrestrial environments through decay and in this way C, N, and P cycle in a process of uptake and release called nutrient spiraling (Newbold et al. 1982). The distance a molecule moves downstream during a complete cycle is its spiraling length, a metric that explicitly relates nutrient utilization to nutrient supply (Newbold et al. 1982). Long spiraling lengths indicate that: 1) nutrient uptake is inefficient because the system is saturated with nutrients and organisms

can no longer fully exploit the incoming nutrient loads, 2) conditions are not optimal for uptake, such as when water flow is too fast, or 3) the stream does not support a community of organisms that effectively processes the nutrients.

In anthropogenically undisturbed Pacific Northwest watersheds, nutrients are ultimately derived from atmospheric and geologic sources, while plants play an important role in the initial uptake of N and P from these sources (McClain et al. 1998). Spatial variation in vegetation, geologic substrates, and human activities drive the variation in stream N and P concentrations and fluxes across the PNW (Wigington et al. 1998; Wise and Johnson 2011). The geology and geomorphology of a watershed and stream channel set the conditions for mineral composition of the groundwater reaching the stream because the shape and slope of the channel and banks affect water movement and velocity. Some bedrock types yield high stream P (Ice and Binkley 2003), leading to high regional P variability in riparian ecosystems and streams. Some types of vegetation can fix atmospheric gaseous N via symbiotic relationships with bacteria in their root systems, and in turn produce more biologically available N than they consume, thereby contributing to N loads in watersheds. A prime example is N<sub>2</sub>-fixing Red Alder *Alnus rubra*, an important source of dissolved N in streams in western Oregon and Washington (Compton et al. 2003; Wise and Johnson 2011; Greathouse et al. 2014).

Nitrogen may occur in organic forms as microbial, plant, or animal tissue and in dissolved organic forms, or, if inorganic, primarily as nitrate (NO<sub>3</sub><sup>-</sup>) and ammonium (NH<sub>3</sub><sup>+</sup>), which are forms that can be assimilated by organisms into organic molecules. Forests in the PNW generally have fairly tight N and P cycles with little N or P lost or leached from the system. Rather, there are low rates of N and P inputs and outputs, but high rates of internal cycling (Sollins et al. 1980; Compton and Cole 1998). Triska et al. (1984) showed that N inputs

to a stream reach in an old-growth forest watershed in Oregon's Cascade Mountains were dominated by dissolved organic N from groundwater (69% of inputs), with litterfall and precipitation playing smaller roles.

Human activities like timber harvest, farming, or urban development alter nutrient cycles (Figure 6.2), producing higher fluxes, shorter storage durations, and higher concentrations of nutrients in subsurface flow, some of which will enter streams. Disturbances through forestry, grazing, agriculture or urbanization can alter the timing and routing of water through a landscape (Tague and Grant 2004), which can influence nutrient uptake and delivery to streams. Agriculture can contribute to excess nutrients in riparian and aquatic ecosystems through increased runoff of N and P from fertilizer and livestock manure (Wise and Johnson 2011). Point sources and urban stormwater runoff are the dominant sources of N within urban areas. For P, geologic materials dominate natural sources, with point sources such as urban runoff, farm manure, and fertilizer important in areas under anthropogenic land uses. Timber harvest increases stream nitrate and to a lesser extent phosphate concentration (Fredricksen et al. 1975; Scrivener 1975; Martin and Harr 1989). These increases generally persist for a short time, although Brown et al. (1973) saw increases in nitrate persist for six years post-timber harvest and burning.

Historically, a major source of allochthonous<sup>1</sup> nutrients and energy-rich carbon compounds was anadromous salmon (Cederholm et al. 1999; Gende et al. 2002). Anadromous, semelparous fish return from the ocean to spawn and die in their natal streams. The mass of every salmon carcass, of which 95% is accumulated in the marine environment (Naiman et al. 2002), is deposited in oligotrophic freshwater environments. The magnitude of nutrient and chemical energy losses to freshwater ecosystems caused by declines in salmon populations can best be appreciated by comparing current and historical salmon run sizes. Gresh et al. (2000)

<sup>1</sup> Allochthonous means originating or formed in a place other than where found. Hence, in the context of aquatic ecosystems, allochthonous nutrients found in a stream originated in terrestrial ecosystems. In contrast, autochthonous means originating or formed in the place where found.

Historically, carcasses of adult salmon delivered approximately 100,000 tons of nutrients to rivers and streams of Washington/Ned Pittman, WDFW

estimated that the current biomass of salmon runs for all Pacific salmon species (Chinook *Oncorhynchus tshawytscha*, Coho *Oncorhynchus kisutch*, Sockeye *Oncorhynchus nerka*, Chum *Oncorhynchus keta*, and Pink *Oncorhynchus gorbuscha*) in Puget Sound, the Washington Coast, and the Columbia River Basin are 25, 5, and 1% of historical biomass (circa early 1900s), respectively. This represents a loss of 122,470 US tons per year (111,104 metric tons) of marine-derived

nutrients and chemical-energy in these watersheds. Naiman et al. (2002) estimated that in the Willapa Bay Watershed the biomass of Chinook, Coho, and Chum Salmon carcasses in streams decreased from 2,920 to 226 US tons (2,649 to 205 metric tons per year), and that marine derived N and P decreased by more than 90%.

Figure 6.2 represents nutrient cycling in a watershed with more human-associated disturbance, including an

absence of salmon returns; by comparing Figures 6.1 and 6.2, changes in the cycling loop and intra-system transfers are evident when salmon are missing. Much of the cycling of marine-derived nutrients is mediated by predators and scavengers that move large amounts of marine-derived nutrients substantial distances into the terrestrial environment either as salmon carcasses or as metabolic waste products, i.e., urine and feces (Naiman et al. 2002). In several small streams on the Olympic Peninsula, Cederholm et al. (1989) observed that Coho Salmon carcasses were consumed by 22 species of mammals and fish (e.g., American Black Bear *Ursus americanus*, Northern River Otter *Lontra canadensis*, Mink *Mustela vison*, Bald Eagles *Haliaeetus leucocephalus*, and Ravens *Corvus corax*), and that 40% of salmon carcasses were moved by scavengers from the water to riparian areas. Flooding also can deposit salmon carcasses in riparian areas (Ben-David et al. 1998). Salmon carcasses provide N and P nutrients for microbes, plants, and animals, and influence all trophic levels in riparian ecosystems (Willson and Halupka 1995; Compton et al. 2006). Trees and shrubs in riparian

areas along spawning sites in the Kadashan and Indian rivers of southeast Alaska derived approximately 23% of their foliar nitrogen from decayed salmon carcasses, and growth rates of Sitka Spruce *Picea sitchensis* were significantly increased (Helfield and Naiman 2001). On average, 17% of the nitrogen incorporated into the riparian vegetation of a stream in western Washington was derived from carcasses of spawning salmon, and significant percentages of marine-derived N (up to 30%) and C (up to 39%) were found in aquatic insects, Cutthroat Trout *Oncorhynchus clarkii*, and juvenile salmon (Bilby et al. 1996).

Other animals subsidize riverine food webs by transporting nutrients across watersheds or by altering the hydrology (Chapter 8 in this document; Naiman and Rogers 1997; Masese et al. 2015). As ecosystem engineers, American Beaver *Castor canadensis* have a significant influence on stream nutrients. Beaver can influence biogeochemical cycles by impounding streams and changing hydrologic regimes and organic matter and sediment transport (Pollock et al. 2007).

Figure 6.2. Nutrient cycle of a disturbed PNW riparian ecosystem and connected stream and upland cropland. Much of the cycling of marine-derived nutrients is facilitated by predators and scavengers that move nutrients into the terrestrial environment either as salmon carcasses or as urine and feces. Modified from Moyle et al. (2009). DIP = dissolved inorganic phosphorus; DIN = dissolved inorganic nitrogen (nitrate and ammonium); DOC, DON, DOP = dissolved organic carbon, nitrogen and phosphorus, respectively.

Retention of total N and P increased 72% and 43%, respectively after Beaver populations recovered in a Minnesota watershed (Naiman et al. 1994) and organic matter (carbon) retention increased three-fold after a stream was impounded by Beaver (Naiman et al. 1988). However, Beaver impoundments also influence N dynamics by flooding riparian forests, creating anoxic conditions in forest soils leading to an increase in denitrification and subsequent reduction in N (Naiman et al. 1988). Elk *Cervus canadensis*, deer (*Odocoileus* spp.), and livestock can also be important sources of N and P when found in close proximity to streams.

Riparian vegetation can affect uptake and delivery of nutrients to streams. Riparian plant roots can slow water movement and stabilize soils as well as take up dissolved nutrients. The types of vegetation and growth patterns in riparian areas determine the amount and timing of litterfall and woody material delivery to a stream. The height and density of vegetation dictate shading and solar input to the stream, thus affecting conditions for plant growth and N and P uptake. The key limiting nutrients for primary production in PNW streams are N and P (Welch et al. 1998), but there has not been enough experimental work conducted across the region to determine precisely when and where this occurs.

---

*Shallow groundwater adjacent to stream channels often is a hot spot for N removal processes and a storage zone for other solutes.*

## 6.1.2. Carbon

The cycling of C in riparian and aquatic ecosystems is complex and can differ among locations and through time because C can be available in different forms and is produced by different sources, thereby affecting its transport and fate. Carbon is tightly linked to N and P, driving biological transformations of these nutrients. Organic C regulates ecosystem functions in streams and rivers because dissolved organic carbon (DOC) is a primary energy source for microorganisms. Riparian vegetation in forests influences DOC composition and contributes a substantial proportion of stream organic C budgets (McDowell and Likens 1988). DOC in streams is a mixture of recalcitrant, (i.e., difficult to process components) and more easily metabolized labile fractions that drive biogeochemical processes involving nitrogen (Kaushal and Lewis 2005). For example, availability of dissolved and particulate organic C can limit denitrification, a microbial process critical to maintaining water quality, which has important implications for managing N in streams (Newcomer et al. 2012). Denitrification occurs only under anaerobic conditions where microbes shift from respiring oxygen to respiring nitrate, releasing nitrous oxide, and inert N<sub>2</sub> gas. These conditions may be ephemeral, fluctuating in response to water tables and associated changes in redox potential (Mayer et al. 2010b).

Anoxic conditions also promote the production of methane. Production of methane and nitrous oxides, increase in riparian areas with increased organic C supply (Kaushal et al. 2014). Dissolved organic carbon also can increase biological oxygen demand, thereby reducing oxygen for fish (Stanley et al. 2012).

Various organic C types from biofilm, leaves, and soil organic matter may have differential effects on ecosystem functions in forested streams (McDowell and Likens 1988), agricultural streams (Royer and David 2005), and urban streams. For example, C derived from

grasses supports more denitrification than C from tree leaves (Newcomer et al. 2012). Because the microbes that influence the transport and fate of N in riparian ecosystems require C as an energy source, C and N are inextricably linked in a biogeochemical sense.

Shading of small headwater streams in forested watersheds can obscure 95% of sunlight (Murphy 1998); hence, in-stream productivity is typically light-limited. Consequently, the main energy source for such streams is allochthonous chemical energy contained in litter from riparian areas (Conners and Naiman 1984; Bisson and Bilby 1998). In headwater streams, litter directly supports an animal community comprised predominantly of invertebrate detritivores which, in turn, support a community of invertebrate predators (Wallace et al. 1997). Detritivores, microbes, and physical breakup convert the coarse particulate organic material (CPOM) of litter to fine particulate organic material (FPOM) which is utilized by invertebrate communities downstream (Bisson and Bilby 1998; Richardson and Danehy 2007). Headwaters comprise 60 to 80% of the cumulative length of a watershed's drainage network (Benda et al. 2005); hence, headwaters contribute a substantial amount of chemical energy to mainstem rivers and associated biota. For example, Wipfli (2005) estimated that every kilometer of fish-bearing stream received enough energy from headwaters to support 100 to 2,000 young-of-the-year salmonids.

Carbon cycles through riparian ecosystems via CO<sub>2</sub> uptake from the atmosphere through photosynthesis, litterfall, decomposition and/or consumption. Riparian litter is a critically important source of C for streams as energy for invertebrates and microbes that form the basis of food webs. Deciduous-dominated riparian forests grow quickly and initially deliver more litter to streams and have a more pronounced seasonal litter contribution than coniferous-dominated forests (Hart et al. 2013). Conifers, however, play an important structural role as large wood in streams. Deciduous species like Red Alder can increase fine litter flux and

*The main energy source for small headwater streams is allochthonous chemical energy provided by leaf litter/Marc Hayes, WDFW*

nutrient delivery to terrestrial and aquatic food webs, thus complementing the year-round shade and wood provided by conifers (Hart et al. 2013).

Chemical energy, required by heterotrophic organisms (those that do not produce their own food from sunlight), is contained within the various C compounds of organic matter. The fundamental effects of organic matter on ecosystem composition, structure, and functions have motivated conceptual theories to describe riverine ecosystems (Pingram et al. 2012). The River Continuum Concept (RCC; Vannote et al. 1980) describes the balance of allochthonous C (produced externally to the stream) to autochthonous C (produced in-stream) in riverine ecosystems from headwaters to mainstem rivers. This balance plays a key role in structuring the invertebrate community. According

to RCC, in narrow headwater streams (first to third order), nearly all C is allochthonous produced by litter from riparian vegetation because shade severely limits the production of autochthonous C produced through in-stream photosynthesis. Because medium-sized streams (fourth to sixth order) are wider, shading decreases, in-stream photosynthesis increases, and the density of litter inputs decreases. Hence, the quantities of allochthonous and autochthonous C may be about equal. In large rivers ( $\geq$  seventh order), shading effects only a small portion of surface water, however, turbidity and water depth limit photosynthetic production. Consequently, according to RCC, the main source of energy in large rivers is allochthonous C from upstream. The RCC also posits that the quantity and quality of organic matter, which changes along the river continuum, affects the composition of the aquatic invertebrate community.

Litter from riparian areas is clearly an important source of limiting nutrients and organic matter for aquatic ecosystems. Consequently, providing adequate amounts of litter to streams is an important issue for riparian area management and addressing this issue requires an understanding of litter delivery into streams. FEMAT (1993:V-26) developed a conceptual model, known as the FEMAT curves, that depicts relationships between riparian ecological functions, including litterfall, and distance from a stream channel. Bilby and Heffner (2016) studied factors influencing litter delivery into streams in young and mature conifer forests of the western Washington Cascades and found that litter travel increased with increasing tree height, topographic slope, and wind speed. They estimated that riparian buffer widths needed to capture 95% of annual litter input from mature conifer forests to streams are between 60 to 83 ft (18 to 25 m) depending on a site's slope and wind exposure. The mean tree height of their three mature forest sites was 154 ft (47 m). Hence, riparian buffer widths needed to meet the 95% capture objective range from 39 to 54% of mean tree height.

Bilby and Heffner (2016) warn that they may have underestimated litter travel distances because they released litter from only the bottom of the tree canopy, but litter travels farther with increasing height, and therefore, litter produced within the tree canopy is likely to travel farther.

While stream flows carry organic matter, insects, and other invertebrates downstream to subsidize food webs in higher order streams, there may also be upstream movement of aquatic organisms that subsidizes food webs in lower order streams. In a Welsh mountain stream, for example, amphipods *Gammarus pulex* showed net upstream movement whereas stonefly (*Trichoptera* spp.) females showed no upstream flight preference, but females moving upstream contained twice as many eggs (Dudley-Williams and Williams 1993). In many cases, however, such as with mayflies (family Baetida), seasonal upstream movements of adults via an aerial pathway are pronounced (Hershey et al. 1993). Such upstream movement of nutrients and chemical energy may be important, but has been little studied.

Large wood in stream channels can affect nutrient cycling by slowing the downstream transport of water, sediment, organic matter, and other materials (Chapter 3). Large wood in riparian areas ultimately decomposes, providing nutrients to the forest floor thereby increasing moisture holding capacity (Harmon et al. 1986). Woody material in streams can be a direct source of labile C to streams that can fuel microbial processes, though most C in wood is relatively recalcitrant, taking years or decades to decompose. Wood slows the flow of water thereby extending the residence time of water in the channel and facilitating accumulation of finer organic and inorganic sediments (Chapter 2) that support biofilms.

### 6.1.3. Nitrogen

Nitrogen is a component of proteins, necessary for all life, and often is a limiting nutrient for both terrestrial and aquatic organisms. N limitation of plant growth is common in PNW forests (Peterson and Hazard 1990). Ultimately, N comes from atmospheric  $N_2$ , which has a very strong triple bond that, aside from lightning and industrial processes, only a few specialized N-fixing organisms can break.

Nearly all N in lotic ecosystems of Washington is derived from allochthonous sources, and in undisturbed headwater watersheds, the source of nearly all N is terrestrial. Nitrogen can enter a river or stream via several pathways: litterfall, movement of soluble N from riparian soils into groundwater and hyporheic zones, and leaching and subsurface transport from upland soils (Compton et al. 2003). Litter may include leaves, leaf fragments, flower parts, fruit, cones, nuts, bark,

branches and twigs (Benfield 1997), however, leaves account for 72% of total litter in broad-leaved forests and 80% in needle-leaved forests (Xiong and Nilsson 1997). Litter may enter surface waters through direct fall, lateral movement along the ground, or mobilization during floods.

For a headwater stream in the western Cascades of Oregon, Triska et al. (1984) found that more than 90% of annual N inputs to the stream were derived from biotic processes in the adjacent forest. Seventy-three percent of N entering the stream was dissolved organic N in water flowing through the subsurface from forest to stream and 21% was contained in organic matter (e.g., leaf litter, needles, and coarse woody debris) from the riparian forest. The headwater stream exported 74% of its annual N inputs to downstream waters; 22% of the exported N was contained in particulate organic matter. Edmonds et al. (1995) found that nitrate concentrations in the waters of an undisturbed watershed were

*N-fixation by Red Alder is an important component of nutrient cycling in forests of western Washington and Oregon/Ned Pittman, WDFW*

seasonal, with in-stream concentrations being highest in the fall and lowest in the summer when N uptake by terrestrial vegetation was greatest.

Red Alder fixes  $N_2$  and enriches soil with N compounds through root and nodule secretions. Red Alder leaves contain N concentrations roughly 2 to 3.5 times greater than leaves or needles of other tree species (Tarrant et al. 1951). Because aquatic ecosystems in undisturbed watersheds are often N-limited, Red Alder can be a major source of allochthonous N to aquatic ecosystems, and more Red Alder litter can increase ecosystem productivity. For example, Wipfli and Musslewhite (2004) found that headwater streams with more Red Alder canopy cover exported greater biomass of both terrestrial and aquatic invertebrates to fish-bearing waters than riparian areas with less alder. This subsidy of prey from headwaters to fish-bearing streams is needed to maintain fish productivity (Wipfli and Baxter 2010).

Nitrogen cycles in the environment through multiple redox states, in solid, dissolved, and gaseous forms, and originates from multiple sources, making for one of the most challenging biogeochemical cycles to monitor and characterize (Figure 6.3). Shallow groundwater adjacent to stream channels often is a hot spot for N removal processes and a storage zone for other solutes (Hinkle et al. 2001; Zarnetske et al. 2011). The groundwater-surface water interface is characterized by dynamic gradients of dissolved oxygen, N, and organic C concentrations where biogeochemical reactions take place, including metabolism of organic C, denitrification, and nitrification (Sobczak et al. 2003). Denitrification is generally considered the most important biological process through which ecosystems lose N. Denitrification, and disturbances like tree harvest and fire, remove N from an ecosystem, whereas N uptake by plants eventually returns N to the system through litterfall or senescence and subsequent microbial decay. Organic C is required as an energy source for denitrification. Small streams can lose nitrate

Figure 6.3. Nitrogen cycle pools and processes in ecosystems.

N efficiently because of their high ratio of streambed area to water volume, which brings more surface water in contact with the hyporheic zone. Small streams have a large cumulative influence on N transformation and loss because they account for most of the stream length within a network (Alexander et al. 2000; Peterson et al. 2001). Larger streams lose nitrate N because of longer transport distances over which more biological reactions can occur that consume N coupled with longer water residence times and higher N concentration which fuels the denitrification along with organic C (Mulholland et al. 2008).

Increased groundwater-surface water interaction can alter dissolved oxygen concentrations and redox conditions (Striz and Mayer 2008; Zarnetske et al. 2012), transporting N- and C-containing organic matter to microbes in subsurface sediments, leading to N loss via denitrification under favorable oxidation-reduction conditions (Hedin et al. 1998). The conditions that favor denitrification may change rapidly over time and space. Therefore, "hot spots" may form where denitrification occurs in small patches of the stream (e.g. under leaf packs) or "hot moments" where denitrification rates are high but for short periods of time due to rapid dynamic water movement (McClain et al. 2003; Vidon et al. 2010). However, biochemical processes in urban riparian soils such as denitrification may be impaired because of increased rates of erosion and limited groundwater-surface water interaction due to high proportions of impervious surfaces (Groffman et al. 2002).

The importance of riparian vegetation on transforming N inputs has been examined (Sweeney et al. 2004; Mayer et al. 2007; Sweeney and Newbold 2014). Riparian area characteristics such as width of vegetation, soil carbon, and hydrologic flowpaths, can influence the amount of N removed. Mayer et al. (2007) surveyed the available scientific literature containing data on riparian management and N concentration in streams and groundwater to identify relations between N uptake and riparian width, hydrological flow path, and

vegetative cover. Removal efficiencies ranged from <0 (i.e., where the riparian ecosystem appeared to be a N source) to 100%, with a median removal rate of 91%. Wide vegetated riparian areas (>165 ft; 50 m) more consistently removed significantly higher proportions of N entering riparian areas than narrow bands of vegetation (0 - 82 ft; 0 - 25 m). The critical conclusions from this review were that riparian areas were effective at trapping and removing N when they were vegetated, wider, and allowed for subsurface movement of water where the interaction of nutrients dissolved in the water had prolonged contact with soils. Therefore, the hydrologic connection of riparian areas and streams is key to effective nutrient capture. Where channels are incised, riparian areas tiled for drainage, or where floodplains are disconnected via reinforced banks or channelization, nutrients will flow downstream with little interaction with riparian areas.

Subsurface hydrology (saturated vs. unsaturated soil conditions) and redox condition appear to be significant determinants of N-removal efficiency, regardless of vegetation (Mayer et al. 2007; Mayer et al. 2010b). When the water table fluctuates in response to precipitation events, buried relict hydric soil may become saturated, producing sub-oxic or anoxic conditions (Hefting et al. 2004; Weitzman et al. 2014), facilitating N removal. Where flow paths move through wetland riparian soils, great potential exists to remove large quantities of N in proportion to the loads (Jordan et al. 2011); where flows occur via deeper groundwater dynamics or via tile

*Riparian vegetation: Red Elderberry *Sambucus racemosa*/ Ned Pittman, WDFW*

drainage, N in solution may bypass the C-rich riparian soils and flow through zones where less potential exists for nutrient removal (Wigington et al. 2005). Hydrologic connectivity between riparian areas and streams is a critical factor in determining N removal rates.

Denitrification rates in the stream channel are linked to the organic C content of benthic sediments, respiration rates, and extent of stream water interaction with the streambed (Alexander et al. 2000; Mulholland et al. 2008), conditions that can be fostered by woody material (e.g., sticks, branches or tree trunks), and debris dams in streams. Woody material may function as microsites or hotspots of elevated biogeochemical cycling including denitrification (Groffman et al. 2005), and provides substrates for bacteria and fungi, which in turn consume N in streams (Ashkenas et al. 2004).

Biofilms are a matrix of algae, bacteria, and fungi embedded in a slick polysaccharide film that coats hard substrates in streambeds. These microbial communities consume, respire, and reduce inorganic N (Mulholland et al. 1995). Physical habitat heterogeneity and the biodiversity of the biofilms influence N uptake (Cardinale et al. 2002; Cardinale 2011). Biofilm structure, composition, and capacity for biogeochemical cycling are influenced by substrate composition, light penetration, nutrient concentration, flow rates, seasonality, sediment composition, and the community of invertebrate grazers in the vicinity (Sabater et al. 2002). Biofilms formed on wood substrates have been found to have higher respiration rates and greater N demand than biofilms developed on rock substrates (Sabater et al. 1998). Lazar et al. (2014) found that biofilms on wood substrates in a forested stream had significantly higher denitrification rates than those on non-organic substrates such as stone. In an old-growth forest system in Oregon, aquatic mosses and biofilm on large wood showed the highest N uptake rates among biota while, both vertebrate and invertebrate consumers took up substantial amounts of N, especially small invertebrate grazers (Ashkenas et al. 2004).

Furthermore, N in the stream was transported to the upland through uptake by terrestrial plants, likely through long, subsurface flow paths, demonstrating a strong link between terrestrial and aquatic systems (Ashkenas et al. 2004).

In addition to the biofilms on the streambed, microbial communities within the hyporheic zone can be hotspots for N dynamics. At the HJ Andrews Experimental Forest in Oregon, Zarnetske et al. (2011) found that the hyporheic zone was an important site for N dynamics in small forested streams, with residence time determining the dominance of different N transformation processes. Water pathways with residence times of less than 7 hours tended to be dominated by DO and DOC use as well as ammonium and nitrate production, while pathways with longer residence times removed N via denitrification. Further modeling suggested that water residence times and oxygen uptake rates of microbes are important determinants of whether hyporheic zones are net sources or sinks of nitrate N (Zarnetske et al. 2012). In large rivers like the Willamette, hyporheic zones can be important areas for nitrate removal from regional groundwater prior to entry into surface flow (Hinkle et al. 2001), as well as important for N removal and cooling as water moves in and out of hyporheic areas on its path downstream (Fernald et al. 2006).

The relationships between land use and N transport and fate can be complex, and are mediated by aquatic and riparian biota. Sobota et al. (2012) showed that N uptake differs substantially across forested, agricultural, and urban streams in the Willamette River basin in Oregon. Most nitrate N in forested streams was transported downstream without being taken up. N storage was high in algal biomass in unshaded agricultural and urban streams but turnover and subsequent recycling back to the stream may ultimately be high (Sobota et al. 2012). Collectively, this work indicates that uptake via heterotrophic organisms living on large wood is critical to long-term N capture in forested streams. Once the canopy is opened up, autotrophic algal production

becomes a more important process for uptake of excess nutrients, which leads to shorter-term storage and potential for negative consequences associated with freshwater algal blooms.

## 6.1.4. Phosphorus

Phosphorus (P) is an important component of adenosine triphosphate (ATP) and necessary for energy transformations in plant and animal cells. Like N, low P availability often limits primary production on land and can be particularly limiting to productivity in freshwater. This is because P tends to form complexes and be retained in soils and thus does not move as readily into ground and surface waters from the landscape as does nitrate N. P cycles in the environment through multiple organic and inorganic forms (Figure 6.4). P occurs in the environment in organic forms (e.g., organo-phosphate and polyphosphates like ATP) in plant and animal biomass, sewage, and pesticides. Inorganic forms of

P, such as phosphate ( $\text{PO}_4^{3-}$ ), and orthophosphate, are biologically reactive and thus can be used directly by plants and microorganisms (Carpenter et al. 1998). Orthophosphate is derived from phosphate-bearing minerals, fertilizers, detergents, and industrial chemicals. In the Pacific Northwest, bedrock is the major source of stream P loads, with fertilizer, manure, and wastewater inputs important in some locations (Wise and Johnson 2011). Overabundance of P can result in abnormally high primary production in water, leading to water quality problems such as algal blooms, production of cyanotoxins, and low oxygen events (Carpenter et al. 1998; Jacoby and Kann 2007).

P is commonly a limiting nutrient in aquatic ecosystems because it is highly insoluble and has an affinity for binding to soil particles. Nevertheless, riparian areas are sources of allochthonous P to streams in undisturbed watersheds. The amount of P that is contributed by riparian areas to aquatic habitats through litterfall

Figure 6.4. Phosphorus cycle pools and processes in ecosystems.

relative to other sources under natural, undisturbed conditions has yet to be quantified for riparian ecosystems in the Pacific Northwest.
